As volume after volume of the new edition of this magnificent work appears, one becomes more and more impressed with two facts: one is that since the first edition appeared the progress of medicine in all its departments has been most wonderful; the other is that this work represents the medicine of to-day as the first edition reprevented that of its time. This means that much of the old matter has had to be rewritten, and that not a small part is entirely new. Many of the articles in each volume are on subjects that were not thought of fifteen years ago, and some of these are so full as to make important monographs of themselves. This large amount of new matter has made it necessary to reduce the space occupied by some subjects that were then considered important, but which now are of little interest; and not a few subjects that appeared in the former edition are omitted entirely in the present one. But the editorial rejections, as far as we notice, have been wisely made, and nothing of importance is omitted. In a volume as large as this one, covering so many subjects by so many authors, it might seem easy to find something to criticise; but we find nothing. The selection of men to write on the various subjects has been wisely made, and the amount of space allotted to each subject has been made with a due regard to its importance or otherwise. The work, when completed, if the volumes yet to come are as excellent in every way as those which have already appeared, will be the most important and valuable encyclopedia of medicine in the English, if not in any, language.

Bacteriological Chart in Colors. For Free Distribution. New York: M. J. Breitenbach & Co. 1903.

This chart, 17 by 36 inches in size and intended to hang on the wall, shows in sixty colored plates the various pathogenic organisms. The chart, we presume, is not intended to be scientifically exact and true to nature in every case, but rather to call attention to the general characteristics of the organisms illustrated. There seem to be included some organisms of doubtful etiologic relations, or at least which are not yet generally recognized. Nevertheless, the chart is one that will prove of interest and value to the general practitioner.

Obstetrical Nursing for Nurses and Students. By Henry Enos Tuley, M.D., Louisville, Ky., Professor of Obstetrics, Kentucky University, Medical Department. Cloth. Pp. 202. Price, $1.00 net. Chicago: G. P. Engelhard & Co. 1902.

This is a very practical little work. The author evidently fully appreciated the needs of the obstetric nurse and has given us a book that, in a compact form, fully supplies all the information the ambitious nurse will need. The limitations of the functions of the obstetric nurse are recognized, consequently she is not encouraged to assume the rôle of obstetrician as well as that of nurse.

Microscopy and Bacteriology. A Manual for Students and Practitioners. By P. E. Archinard, A.M., M.D., Demonstrator of Microscopy and Bacteriology, Tulane University of Louisiana, Medical Department. Series Edited by V. C. Pedersen, A.M., M.D., Instructor in Surgery and Assistant Anesthetist at the New York Polyclinic Medical School and Hospital. Illustrated with 74 Engravings. Cloth. Pp. 210. Philadelphia and New York: Lea Brothers & Co.

All that is claimed for this work is that it affords a brief but clear presentation of the essentials, a thorough knowledge of which is necessary as a foundation for a sound superstructure. It is a practical little book.

Medical Organization.

Marshall County (Miss.) Medical Association.

This was organized at Holly Springs, July 30, under the guidance of Dr. K. P. Perkins of Batesville, councilor. Dr. R. H. Peal was elected president and Dr. Robert A. Seale secretary-treasurer.

Franklin County (Iowa) Medical Association.

The officers of this new organization are: President Dr. Charles H. Tidd, Geneva; secretary, Dr. J. Clinton Powers, Hampton; treasurer, Dr. Abraham J. Hobson. Nearly all the practicing physicians of the county are members.

Lafayette County (Miss.) Medical Society.

This was organized at Oxford, July 29, with the assistance of Councilor K. P. Perkins of Batesville. Dr. Wade S. Banks, Abbeville, was made president; Dr. F. Baxter Linder, Oxford, vice-president; Dr. Peter W. Rowland, Oxford, secretary and treasurer.

De Witt County (Tex.) Medical Society.

This was organized July 30, half of the eligible physicians of the county participating. Dr. Joseph M. Reuss, Cuero, was elected president; Dr. Wm. C. Swain, Cuero, vice president; Dr. W. R. Gillett, secretary; and Dr. Oscar J. Mugge, Cuero, treasurer.

Titus County (Tex.) Medical Society.

This society was organized at Mt. Pleasant, Aug. 4, under the direction of Dr. Holman Taylor of Marshall, councilor for

the district. Dr. S. R. Crabtree was elected president, Dr. Thomas S. Grissom, vice-president, and Dr. Walter J. Matthews, secretary.

Madison County (Ohio) Medical Society.

At London, July 31, this society was organized with these officers: Dr. H. S. Quinn, West Jefferson, president; Drs. Wm. H. Christopher, London, and A. J. Welsh, Mt. Sterling, vice-presidents; Dr. Albert Strain, London, secretary and treasurer. Dr. Theodore W. Rankin of Columbus was present and made an address.

Harris County (Tex.) Medical Association.

Under the guidance of Drs. John T. Moore, Galveston; Witten B. Russ, San Antonio, and Walter Shropshire, Yoakum, this association was formed at Houston, July 27. Dr. Edward M. Armstrong was elected president; Dr. James H. Bute, vice-president; Dr. J. Edward Hodges, secretary, and Robert T. Morris, treasurer.

Societies.

Medical Society of the Missouri Valley.—The date of meeting in Omaha has been changed from Sept. 17 to Sept. 14 and 15, 1903.

American Association of Obstetricians and Gynecologists.—This association will hold its sixteenth annual meeting at Chicago, Sept 22 to 24, 1903, under the presidency of Dr. L. H. Dunning, Indianapolis. The Auditorium Hotel Annex has been selected for the headquarters, the management of which should be addressed concerning rooms and rates. Dr. J. B. Murphy, 100 State street, is the chairman of the committee of arrangements, and will gladly furnish any information to members and guests on application. Dr. Murphy may also be addressed relating to accommodations at the Auditorium Annex or other hotels.

Massachusetts Association of Boards of Health.—This association was entertained at Gallops Island, Boston Harbor, at its quarterly meeting, July 30, by the Boston Board of Health. This island is the quarantine station of the port. One paper read was by Dr. B. R. Ricards on the value of disinfectants, a report of his experiments in the Boston Board of Health Laboratory. His evidence goes to prove the great efficiency of carbolic acid and allied cheaper products. Prof. Wm. L. Underwood of Belmont, a lecturer at the Massachusetts Institute of Technology, gave a very interesting lecture with the stereopticon on mosquitoes. He has discovered a big mosquito in the woods of Maine which will devour culex and anopheles and leaves man alone. Until its practical usefulness in this way is demonstrated, however, he commended the use of a pyrethrum smudge, much in the same way it is now used for that purpose in Havana, Cuba.

BRITISH MEDICAL ASSOCIATION.

Seventy-first Annual Meeting, held at Swansea, Wales, July 28 to 31, 1903.

(By Our Special Representative.)

(*Continued from page 463.*)

The President, Dr. Thomas Frederick Griffiths, Swansea, in the Chair.

First General Meeting.

The first general meeting of the members was held Tuesday, July 28, at 2 p. m., in the King's Hall.

The financial statement for the year 1902 was presented, showing a profit for the year of about $2,400.

The first annual representative meeting was held at 3:30 p. m., with Sir Victor Horsley as chairman. Among the reports considered at this meeting was the report of the council which dealt with the imperial vaccination league, the *British Medical Journal*, the superannuation fund, scientific grants committee, the special chloroform committee, the medico-political committee, the vaccination acts, etc.

The president's address was delivered at the Albert Hall at 8 p. m. by President Griffiths, who selected for his subject the following:

The Evolution of Antiseptic Surgery and Its Influence on the Progress and Advancement of Bacteriology and Therapeutics.

Among other things he described the growth of antiseptic surgery. He said the architect has been very rightly called into service to further the practical application of Listerism. This is especially to be noticed in the construction of modern hospitals, and in the addition of new operating theaters to old institutions. They are invaluable in surgical work.

Some thirty-six years ago the mortality from major operations in the London hospitals was about 33 per cent. This high mortality, after major operations, is now reduced to about 3 per cent., and, after minor operations, practically to *nil*, as the outcome of Lister's antiseptic surgery.

BACTERIOLOGY AND IMMUNITY.

The brilliant discoveries of Pasteur and the evolution of antiseptic surgery by Lister gave a great impetus to the study of bacteriology, with the result that new and unexpected discoveries were made as to the part played by bacteria in nature. These micro-organisms have a definite and important place in the scheme of nature. They are distinctly separated by gradation from both the vegetable and animal kingdoms. They form a kingdom of their own which may be termed the "bacterial kingdom." Their very existence appears to be antagonistic to both animal and vegetable life. Their object in nature is evidently one of destruction—the breaking up of complex molecules of animal and vegetable substances into simpler combinations. They are Nature's scavengers, and undoubtedly they are the causal agents of all the communicable diseases to which flesh, and not human flesh alone, is heir.

The varieties of bacteria, differing in size, form, action, character and power for good or evil, are almost endless.

A bacterium may have two states or stages of existence. One is the active or vegetative stage, and the other the spore or resting stage. In the latter state, which may be compared to that of a hard nut or seed, it may remain dormant for a long time until the surroundings favor its development into the active state. This, he showed, has an important bearing on the treatment and etiology of specific diseases.

Pasteur's and Davain's discoveries led up to Koch's investigation. Davain discovered bacteria in the blood of animals suffering from anthrax in 1863, thus confirming the observations made by Pollender in 1849. Koch repeated the experiments and finally established in 1876 the causal relationship of bacteria and disease. Tuberculous disease had been proved by Villemin to be inoculable, and in some countries it had long been believed to be infectious, but it remained to Koch to demonstrate, in 1882, that tuberculous disease was due to the agency of micro-organism. He proved that a bacillus played a part in the production of tuberculosis which is analogous to that which is played by torula cerevisiæ (yeast bacillus) in fermentation. The tubercle bacillus feeds, grows, multiplies and produces its toxin at the expense of the surrounding tissues, very much in the same way as the yeast bacillus feeds, grows, multiplies and produces its toxin (alcohol) at the expense of the saccharin solution in which it is placed. The principle discovered by Pasteur in the processes of fermentation and putrefaction was proved, after years of close investigation by Koch, to be absolutely identical in the development of tuberculous disease in the animal body. He demonstrated the bacillus in the tissue, and cultivated the organism outside the body, and observed the formation of the toxin. The same remark may be applied to diphtheria (diphtherization). Diphtheria bacillus grows, feeds, and multiplies on the mucous membrane and there forms its toxin.

THERAPEUTICS.

Both bacteriology and Listerism have greatly helped to advance our knowledge of the action of medicine. Therapeutics have now been raised in many departments from the plane of empiricism to that of science. Peruvian bark, the active principle of which is quinin, was accidentally discovered to be of great value in the treatment of malarial fever. The discovery was the result of observation, but the knowledge

gained was entirely empirical. Prior to the discovery of the hemameba and the observation of its action on the red blood corpuscles, and until the listerian property of quinin was ascertained, we had no idea how the drug acted as a curative agent. It is now evident that it acts simply as an antiseptic in destroying the malarial parasites which are conveyed to the human body by mosquitoes, and it is now very doubtful whether it has any other beneficial action as a therapeutic agent. The world is greatly indebted to Dr. Manson and to Dr. Ross for their discovery of the part played by mosquitoes in the causation of malarial fever.

Salicin.—Very much the same remarks may be applied to salicin, salicylic acid, and the salicylates, which are powerful antiseptics. The discovery that these drugs were specially valuable in the treatment of rheumatic fever was accidental also. It is now acknowledged that rheumatic fever is due to a micro-organism which probably gains access to the circulation through the tonsils or mucous membrane of the pharynx. Sore throat is a frequent precursor of acute rheumatism. It is probable that scarlatinal sore throat predisposes the patient to infection by rheumatic micro-organisms, over which the salts of salicin have a lethal action.

Mercurial salts are the most efficient antiseptic agents we possess in surgical practice, and it may be argued that the therapeutic action of mercury, when administered internally, is to be accounted for to a great extent by its antiseptic property; hence its specific action on syphilis, which is now stated to be a bacterial disease. It has been recognized for many years that mercury is a valuable remedy in tonsillitis, which is also, no doubt, caused by micro-organisms. Dr. Jamieson of Edinburgh pointed out some years since that mercuric chlorid is most valuable as a bactericide in the treatment of scarlet fever.

Other examples were cited.

SANITATION.

Increased infant mortality and diminished birth-rate are two ugly facts which are not to the credit of our country or of modern civilization. The increased mortality among infants is due to diarrhea and enteritis, and it has been found that the increase due to these two causes is seven times greater in towns than in the country. It has also been found that the mortality from diarrhea is much greater among infants artificially fed than among those which are fed at the breast alone or in part. No doubt much of this increased mortality is due to the ignorance and carelessness of mothers and nurses; but it is also an illustration of a defect in sanitary administration due to the optional character of the acts and regulations. There are in existence model rules and regulations for the cleanly and sanitary conduct of dairy farms, which, though they have been approved and sanctioned by the local government board in England, are not adopted, or, where they have been formally adopted, are not enforced in rural sanitary districts. The medical officers of health of our great cities complain that, owing to the neglect of rural sanitary authorities, the milk supplied for consumption, especially in the poorer quarters of large cities, is often either decomposing or putrescent.

Notwithstanding the defects in the administration of the Public Health Act, the country is often under a debt of gratitude to sanitary authorities and medical officers of health for protecting our shores from the invasions of plague and cholera from time to time. The importation of plague to Glasgow and to the London docks, a couple of years ago, is still fresh in our memories, and physicians have not yet forgotten the feeling of relief experienced when they were assured that the causal agents had been destroyed and that the people had safely escaped a terrible calamity. Great credit is due to the sanitary authorities for their promptitude, energy and determination in the performance of their duty on these occasions. The same may be said of our local authorities generally when an epidemic of smallpox, typhoid fever, or some other infectious disease attacks a populous district. Unfortunately the public is apathetic in these circumstances; it must be hard hit, and many lives must be lost, before it wakes up to realize the situation, and give material help to the medical officer. People are indifferent and accustomed to the endemic and preventable diseases persistently destroying a large percentage of the population. This may be attributed to three causes:

1. The absence of a strong central authority.
2. The ignorance, apathy and prejudices of the smaller authorities.
3. The objections and the loud protestations of faddist and conscientious objectors to vaccination, objectors to the Contagious Diseases Act, objectors to the advancement of medicine by experiments, etc.—a class of persons who, regardless of the consequence to others, claim freedom to do as they please in matters pertaining to health, freedom to do what is unjust and wrong, freedom to endanger the lives of others.

He said it is evident that the reform needed is greater central authority and greater power to county councils over public health administration within their respective areas.

The county councils, urban and rural sanitary authorities should be under compulsion to appoint medical officers of health who should be precluded from private practice and should have power to compel the combination of small sanitary authorities into conjoint areas sufficiently large to secure the services of an efficient medical officer who should give his whole time to public health work. The service should be sufficiently tempting to induce some of the best talent in the profession to enter it. One of the duties of the medical officer should be to deliver popular lectures on sanitary questions and hygiene generally, in his district for the purpose of educating the public on the vital importance of observing the ordinary laws of health.

Infective and Infectious Diseases.

The address in medicine was delivered by Frederick T. Roberts, M.D., B.Sc., F.R.C.P., London, who stated that this subject is one that appeals to the entire profession in all its different branches, and by no means least to the general practitioner.

PRACTICAL ETIOLOGY.

The first question to be determined from the point of view of practical etiology is whether a particular disease is infectious, in the true sense of the term, or not? In the next place, it is very desirable, with regard to each individual infectious disease, to have as definite a knowledge as possible concerning its period of incubation; the degree of infectiousness; and the period of infectivity, that is, how long infection lasts in a particular case? In relation to many of the best known affections belonging to this group, these points have been now established fairly accurately, but there is still much to be done in this direction.

The most important and striking advance which has been made in relation to the practical etiology of infectious diseases is in our knowledge of the sources, modes and channels of infection, both generally and with reference to individual members of the group; of personal predisposing conditions; and of the external circumstances which favor or promote their endemic and epidemic prevalence.

The question of the communicability of certain infectious complaints from person to person through the atmosphere is an extremely important one, especially when a number of individuals are aggregated togther; as well as the distance to which the contagium can be thus conveyed, and the agencies which assist in its dissemination. This question is by no means settled in not a few instances. He referred particularly to typhoid fever and smallpox. While typhus fever has always been regarded as a disease strongly infectious from person to person, typhoid fever has been practically dealt with by the large majority of the profession as being free from danger in this way. Now, however, the tendency undoubtedly is, and probably rightly, to be much more careful as regards enteric from this aspect, and there is a growing objection to the admission of typhoid patients into the ordinary wards of general hospitals. Smallpox is still more important. This complaint is highly infectious through the atmosphere, but how far it can be thus carried, particularly from a smallpox hos-

pital or hospital ship, and the influence of winds in conveying the infective agent, is another matter, and may involve troublesome or even momentous consequences. He had noticed in the medical press recently directly contrary opinions on this question, expressed by those who apparently have had equal experience and opportunities of arriving at a practical conclusion. How far emanations from drains, sewers, defective water closets, and the like can produce so-called "blood poisoning" and other indefinite infective conditions, is another question which needs clearing up.

Passing to the more practical results of modern investigations as to infection, he called special attention to the following facts:

1. As a starting point infective micro-organisms have been found and demonstrated in the blood; in certain secretions; in the excreta, urine as well as feces; in the cutaneous structures or shed epithelium; possibly in the expired air; and in specific lesions, morbid products, and discharges from the body of various kinds. Hence we can readily understand how and why most of the diseases with which these organisms are associated are likely to be transmitted from individual to individual; how the infected materials may contaminate fomites, and be thus conveyed far and wide; how they retain their activity in a dried state for an indefinite period, thus rendering apartments or other places infectious; and how they may be "airborne," being carried about by atmospheric currents or winds, and afterwards either inhaled or swallowed by persons, it may be, far removed from the original source of infection, remote epidemics being thus not uncommonly originated.

2. The communicability of certain grave diseases by the contamination of drinking water in different ways, but especially by admixture of infected excreta, is an established fact the importance and far-reaching consequences of which it is impossible to estimate or realize in any adequate degree. Why such contamination should take place is often obvious enough, but it is rather startling to be told that unsuspected and most inviting "spring water" may be a highly dangerous source of enteric fever.

3. One of the most striking additions in modern times to our knowledge regarding the conveyance of infection is in relation to food. In this connection milk and its products stand out very prominently, not only on account of their frequent contamination by infectious materials, probably mainly from the deliberate addition of tainted water to milk, but also because this valuable food may convey organisms directly from diseased animals by whom it is secreted.

4. The rôle which different animals play in the transmission of infectious diseases to man is another aspect of the subject on which modern observations and researches have thrown remarkable light. The relationship in this respect of such diseases as hydrophobia and glanders has long been recognized. The idea of direct infection through the milk or flesh of infected animals is of comparatively recent date. The danger of infection being carried directly by domestic animals, such as birds, cats and dogs from person to person, or perhaps because they themselves are suffering from certain diseases, is not yet appreciated as it ought to be. The rôle played by such unwelcome "large vermin" as rats and mice in relation to plague and probably some other complaints is now familiar to all. Flies, cockroaches and the smaller but too well-known personal vermin may no doubt be instrumental in conveying infection in certain cases, and flies may thus taint food. But the most remarkable and important revelations which modern investigators have given us as to the transmission of infection by animals are those relating to mosquitoes. The discovery and demonstration of the connection between these minute torturers of humanity and malaria, in which Sir Patrick Manson and Major Ross have taken such a prominent part, has already worked incalculable good, and promises in the future to revolutionize the conditions of life in many parts of the world, to the inestimable advantage of the communities who are native to the district, as well as of Europeans whom circumstances compel to reside there. The same statement applies to yellow fever, and probably to other affections prevailing in climates and localities where mosquitoes abound.

5. The question of the relation of infection to soil, place, and particular houses or groups of houses, is a very important one, but about which there is at present much that is uncertain and indefinite, and that needs to be worked out more fully before any positive conclusions can be arrived at with regard to individual diseases.

6. Another most important aspect of infection, from a practical point of view, is the fact that we are every one of us always carrying about in various parts of our bodies microbes, which while habitually innocuous and non-virulent, may under favoring conditions, so far as they are concerned, become extremely virulent, or possibly specific, to our personal undoing; or we may even be harboring in our mouths, throats, noses, ears and thereabouts specific germs by which, quite unintentionally, we are liable to infect others at any time, while we ourselves go scot free.

7. Lastly, he referred to the progress made in our knowledge of the channels of entrance of microbes into the system, and the modes in which they are disseminated.

TREATMENT.

There are certain special questions bearing on the treatment of infectious diseases which he could not pass over without brief comment.

1. *Hydrotherapy and Allied Methods.*—Dr. James Currie of Liverpool strongly advocated and carried out the treatment of fevers on a considerable scale by baths and douches. This treatment fell into practical desuetude, and, indeed, was generally looked on with aversion and dread. In modern times, however, it has not only been revived, but numerous other methods for applying cold to the body, either generally or locally, have been added, not only by means of water, but also of ice and cold air. These methods are now generally recognized and extensively adopted, probably more on the Continent and in the United States than in this country, even in the treatment of many of the ordinary fevers, but especially in the more severe cases; and the local application of ice is strongly advocated in acute pneumonia and other inflammatory infective diseases. While of great value as antipyretics they have other important beneficial actions. Regarding hydrotherapy and allied measures in the treatment of infectious diseases, every medical practitioner ought to be familiar with them, and be able and ready to carry them out when required. The milder methods, such as sponging the skin or applying ice locally, are easily practiced and are often of the greatest service.

2. *External and Local Treatment.*—The treatment of external or local manifestations of particular infectious diseases, such as scarlatina, smallpox or diphtheria, affords legitimate ground for differences of opinion, and it is often puzzling to determine what is best to be done for such conditions when one reads the different methods of treatment advocated by different experienced authorities. The measures to be adopted must be determined very much by the particular views of the practitioner, guided by judgment and discretion, and modified by the special circumstances of each case. Antiseptics and disinfectants are employed with great advantage as local applications for various purposes. How far the light treatment, the *x*-rays, or particular color rays are going to help us, can not be definitely determined at the present time. Just now the subject has come very prominently before the profession and the public, and the "red-light treatment of smallpox," which, however, is by no means a novelty, so strongly advocated by Professor Finsen is attracting special attention, as well as some adverse criticism. What we may expect, also, from that wonderful, newly-discovered element, radium, it is impossible to foretell, but we must be on our guard against accepting statements as to its marvelous curative effects by irresponsible observers.

3. *Vaccines: Serumtherapy.*—What would, no doubt, be generally regarded as the most vitally interesting and important question of modern times bearing on the prevention and treatment of the entire group of infective diseases, is that of "serumtherapy," using the term as an inclusive one, which has

come as the natural outcome of the microbic theory, and is founded, on the whole, on reliable bacteriologic researches and experiments, supported by the results of practical experience in living subjects.

Evolution of Abdominal Surgery.

The address in surgery was given by A. W. Mayo Robson, F.R.C.S. Leeds, who detailed his observations on the evolution of abdominal surgery from personal reminiscences extending over a third of a century and the performance of 2,000 operations.

The rise and progress of abdominal surgery has centered more around ovariotomy than any other branch of work, hence he reviewed the evolution of that operation, calling it the battlefield of abdominal work.

Under perfected technic and a judicious combination of asepsis and antisepsis, ovariotomy has become one of the most successful major operations in surgery, and has paved the way for other equally great triumphs within the abdomen.

It has proved a truly beneficent procedure, and has not only saved thousands on thousands of valuable lives, but has restored to their families sound and healthy very many of the wives and mothers and daughters of nations.

The discovery of the frequency of perforative appendicitis, of perforating gastric ulcer, and of other peritoneal catastrophes is gradually abolishing the term acute peritonitis for the more rational one of acute peritoneal infection, for the treatment of which surgery alone is of any use, and even for it to be of service operation must not be long delayed.

These more rational views of pathology and treatment have originated and developed within recent years, and he could recall case after case, during his student days, in which peritoneal catastrophes ended fatally, where now surgeons should, by timely interference, give a fair chance of life. Could anything show this more definitely than the results of treatment of perforated gastric ulcers, which if operated on at once would would have hardly any mortality, if within 12 hours of rupture have a mortality of 16.6 per cent.; if within 24 hours, 63.6 per cent.; if within 36 hours, 87.5 per cent., and if delayed for 48 hours will only rarely succeed; or to give another example, than the results of surgical treatment of the intestine in typhoid fever, alas too seldom resorted to.

In injuries of the abdomen by penetrating wound, whether stab or bullet wounds, the resulting troubles are from infection, either directly through the instrument causing the injury or by perforation of one of the hollow viscera and escape into the peritoneal cavity of the septic contents; how much more rational it is to consider this as an infection and immediately to set about the removal of the poison and the repair of the damage, if it can be done under conditions favorable to success, than to treat it as peritonitis and rely on so-called antiphlogistic remedies. Few greater triumphs of scientific surgery can be shown than some of the remarkable cases of visceral injury, where stomach, bowel, liver, gall bladder, and other viscera have been perforated, either by bullet or some other sharp instrument, and in which operation has been successfully performed, before infection has had time to occur.

Appendicitis of the acute, perforating, or gangrenous type comes on so suddenly as often to constitute a peritoneal catastrophe, and in a proportion of cases terminates fatally in so rapid a manner that the diagnosis is made only with great difficulty, or not at all. Such cases, when he was a student, went undiagnosed, and death was ascribed to peritonitis simply, a sufficient diagnosis in those days; and it was not till 1886 that anything was heard of this lethal malady, which, though it has slain its tens of thousands, is now, thanks mainly to the labors of Fitz of Boston, who laid the foundation of modern knowledge of the subject, brought under subjection in a very large percentage of cases.

The disease is said to be on the increase, but he is not at all clear as to the truth of this, as there have been buried in literary records for generations, fairly accurate accounts of dangerous inflammations occurring in the right iliac fossa and described vaguely as typhlitis, perityphlitis, paratyphlitis, etc., and both Copland and Burne in 1837 gave accurate descriptions of perforative appendicitis and its consequences.

It is certainly more frequently diagnosed and more scientifically treated than it was, and it is a comfort to know that the operation, when undertaken early, is attended with an encouraging amount of success, and, as shown by Sir Frederick Treves, when treated in the quiescent period it is almost devoid of risk. Arguing from his own experience of operations in the quiescent period in a large number of cases without a death, and from that of many other surgeons at home and abroad, he has no hesitation in saying that had he an attack of appendicitis he should prefer accepting the infinitesimal risk of removal of the organ directly the attack was over to the decided risk of waiting for the next seizure, which might be one of the acute type.

SURGERY OF THE LIVER, STOMACH AND INTESTINES.

After discussing hysterectomy, he turned to the liver and stomach.

The surgery of the liver was until recent years limited to the evacuation of abscesses and hydatids, and it is interesting to note the evolution of the various methods following closely one on the other; of emptying by trocar or aspirator; of opening by caustic or thermo-cautery; of incision *à deux temps;* and, lastly, of the method which we now generally adopt—hepatotomy, or direct incision of the organ after reaching the liver, either through the abdominal parietes, or, if necessary, through the thoracic wall—an operation the credit of which must be given to Lawson Tait.

The surgery of the stomach is still more recent than that of the gall bladder, but unlike gall-bladder work, which was successful from the outset, the way to success in gastric operations has been paved with many failures, and only recently has the surgeon been able to show what can be done in this branch of work.

He is firmly convinced that many deaths are ascribed to cancer when the disease is inflammatory and perfectly curable by the operation of gastroenterostomy without removal of the tumor; this he could prove from his own experience in patients now living and well several years after an operation, which at the time was thought would be only of a palliative nature.

Until quite recently gastric ulcer, except for one or two of its complications, has been considered to be a subject for medical treatment from first to last. The profession is, however, becoming awakened to the fact that it is not the trifling ailment it was once considered to be, and that it should from the first be taken seriously, for it is in the early stages that medical treatment can be employed to the best advantage, and in the later stages that general treatment is so often followed by relapse or by serious complications.

The pancreas had practically received no attention from a surgical point of view up to Senn's classical experimental work in 1886, and even for some time after that the only interest centered around cysts, so that Greig Smith, writing in 1896, said, "The experience of the last ten years has added little to the work of Senn of Chicago." But what do we see to-day? That the subject is of such magnitude as to need a volume of considerable size to adequately deal with its pathology and surgical treatment. He himself has operated on nearly a hundred cases of diseases of the pancreas of various kinds.

Acute pancreatitis is one of the most serious and fatal of diseases, often coming on with startling suddenness, and it is astonishing how it can have escaped the notice of pathologists until so recently. Fortunately surgery has been able to interfere beneficially in some of these cases, especially those ending in suppuration, and as our knowledge of the subject increases we shall be able to do more both in the way of prevention and cure.

The surgery of the intestines provides the most varied and difficult field of work in the abdomen, and as the ordinary methods adopted in general surgery here need modification, the evolution of intestinal surgery has been accompanied by infinite variety in detail.

The interrupted suture at first employed occupied so much time in application that many modifications were soon introduced, and in 1885 Mr. Bishop showed there were no fewer than thirty-three distinct methods of enterorrhaphy, and since probably as many more have been introduced.

In 1887, Senn's plates were employed to facilitate the process of intestinal anastomosis, and he remembered what a great impetus was given to the surgery of the intestinal canal by Dr. Senn's very able paper and demonstration at the International Medical Congress in Copenhagen. In 1892, being dissatisfied with the methods then in vogue, he invented a decalcified bone bobbin shaped like a cotton reel, which would form a temporary splint around which to apply two continuous sutures, one to the serous and another to the mucous margin of the new openings; which method has proved most useful, and he feels sure has ministered to whatever success he has had in this line of work.

The continuous sutures applied over the bone bobbin considerably shortened the time of operation and left the union so safe and secure that in a large number of operations since performed on the hollow viscera, he has continued to employ it with great satisfaction. As illustrating its utility, the series of cases of posterior gastro-enterostomy performed by him up to the end of last year were all done by this method; and, in the four cases that died, the union, as proved by necropsy, was perfect; moreover, he knows that the anastomotic opening has not the tendency to contract that occurs after some of the other methods, and as the bobbin dissolves within two or three days no foreign body remains to cause further trouble. In end-to-end junction of the divided bowel in enterectomy the decalcified bobbin has given him equal satisfaction, and, though from the nature of the cases the actual operative mortality has been greater, yet in no case has the result been due to imperfect coaptation.

In 1892 Dr. Murphy of Chicago invented his well-known metal button, which, since it is employed without previous application of sutures, can be used very quickly, and by its distinguished inventor, as well as in the hands of other surgeons it has been adopted with great success. The two chief disadvantages it presents are, first that it is necessarily associated with sloughing of the compressed and coapted ends of the bowel, next that a foreign body is left in the canal, which sometimes produces ulceration and other troubles, and thirdly that the opening has been found in some cases to contract and necessitate a further operation. Along with many other surgeons he gave it a thorough trial, but soon reverted to the method of suture round a bobbin, and the general trend of opinion is now to rely on simple suturing with or without any mechanical support.

For the rational treatment of intestinal obstruction we owe much, first to the anatomic researches of Sir Frederick Treves, and secondly to his admirable work on the pathology and surgery of the subject.

At the present day the differential diagnosis has been so well worked out, and the technic of operative work so much improved, that no physician or surgeon long delays resorting to operation if relief be not soon obtained, and the results as shown by numerous reports, amply justify the change.

PREGNANCY.

Among the great advances of surgery in the period in question has been the successful treatment of many of the anomalies of pregnancy; for instance, the eminently satisfactory results now obtained in that ancient operation, cesarean section, where at one *séance* two, or sometimes three, lives are saved, and which in the hands of Murdoch, Cameron, Leopold, Sanger, and other operators has been done in recent years with an extremely small mortality, whereas in the large maternity hospitals in Paris during half a century before the aseptic era, although the operation had been done sixty times, in no instance had the mother's life been saved, and in England the operation for similar reasons was condemned absolutely. He knows of no operation that has given greater satisfaction than this one, for the patients are eternally grateful, which is truly the highest reward of the surgeon.

THE SURGERY OF THE KIDNEYS AND URETERS.

The most recent advance in renal surgery has been in the treatment of chronic nephritis or Bright's disease, which was first drawn attention to by Mr. Reginald Harrison, who recommended renal puncture or incision in certain cases of chronic albuminuria, but to Dr. Edebohls of New York must be given the credit of adopting an original operation for the treatment of Bright's disease. He in 1898 deliberately exposed both kidneys, stripped their capsule, and fixed them in position, in a young woman of 26. Frequent examinations during the five years showed in every instance normal conditions, and the patient has recently married and is well. In March of this year Dr. Edebohls reported 51 cases of renal decapsulation, and in 47 of these cases both kidneys were operated on at the same time. Out of this large number, 22 are said to be improving from three to fifteen months after operation.

As yet it is too early to pronounce a definite opinion on the procedure, but it is an undoubted fact that decapsulation does effect some improvement in this serious malady, and it may possibly prove effectual in saving life in those terrible cases where suppression of urine comes on after some trifling operation, such as catheterism, or after a chill, or in scarlatina; just as surgery has effectually stepped in and saved life where suppression was due to obstruction of both ureters. No patient ought to be allowed to die from suppression of urine without the surgical question being considered.

Ureterotomy for stricture and valvular obstruction, leading to hydronephrosis, was an innovation first successfully performed by the late Christian Fenger of Chicago in 1892, and since done by others; for instance, in a case of this kind, where the kidney merely formed a shell over an enormously dilated pelvis, he found the ureter strictured and coming off from the upper part of the dilatation. By dividing the stricture, bringing the edges together transversely, and afterward constricting the large sac by a number of running sutures, the kidney was saved, and has since performed its work satisfactorily.

SEROTHERAPY.

It was hoped that the principle of serumtherapy which has been so eminently successful in the case of diphtheria would also be applicable in the case of bacterial diseases. Unfortunately, however, hopes have not been fulfilled, as not only have the sera thought to be applicable to other diseases failed to do good, but in some cases actual harm has resulted. Nevertheless, the principle is capable of being worked out, and doubtless ere long will be, and he feels sure that it is destined to revolutionize practice in dealing with localized bacterial invasions.

An immense impetus has been given to this line of work by the investigations of Dr. Macfadyean, who, utilizing the discovery of the liquefaction of air made by Professor Dewar, and the intensely low temperature that can be obtained through its employment, has succeeded in grinding up typhoid organisms and liberating the bacterial contents, which can be used as protective vaccines without the danger of introducing living organisms that would tend to intensify and continue the disease.

Of the treatment of streptococcus infection, such as erysipelas and other diffuse inflammations, by the antistreptococcus serum surgeons would probably point to some excellent as well as to other uncertain results; but as improvement in the preparation of the antitoxin occurs, and as their knowledge of when and how to use it is increased, they would be able to calculate on more certain results. At the present time surgeons are finding the injection of the serum of service in immunizing before operating in certain regions, such as the tongue, mouth, throat, and rectum, where asepsis can not be secured with certainty.

In conclusion he said he had tried to show what a close connection exists between the science and art of our profession, and how very necessary it is, if we are to continue our march of progress, that experimental research should not only be untrammeled by factious and unreasoning opposition, but that it should receive greater recognition, encouragement, and support at the hands of the public.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Treatment of Cough.

Pfromm, in *Med. Bul.*, recommends the following combination in the treatment of cough due to an acute bronchitis:

℞. Codeinæ sulph.	gr. 1/16	004
Antimonii et potass. cit.	gr. 1/24	0025
Pulv. opii et ipecac.	gr. 1/12	005
Ext. gentianæ	gr. i	06

M. Ft. capsula No. i. Sig.: One such capsule to be taken every hour until nausea appears; then one every two hours.

The author states that, with this treatment, the cough begins to lose its harshness and the bronchial secretion is increased within thirty-six hours, when the stimulating expectorants should be substituted, such as scilla, ammonium chlorid, ammonium carbonate and terpin hydrate.

In the treatment of chronic bronchitis the derivatives of turpentine are of service. The oils of eucalyptus, santal wood and thyme are also successfully employed in chronic bronchitis. In prolonged and stubborn cases of acute bronchitis the following is valuable in relieving the cough and promoting elimination from the mucous membrane:

℞. Codeinæ sulph.	gr. 1/8		008
Ammon. chloridi	gr. v-x		30-.60
Syr. senegæ	m. xv	1	
Syr. scillæ	m. x-xv		65-1.
Syr. pruni virg. q. s. ad	3i	4	

M. Sig.: At one dose, to be repeated every two or three hours.

In chronic bronchitis the following is advised by the author:

℞. Codeinæ sulph.	gr. 1/4	015
Olei eucalypti		
Terebeni, āā	m. iii	20

M. Ft. capsula No. i. Sig.: One such capsule to be taken four times a day.

Dyspnea in Chronic Bronchitis.

According to Bruhl, in the *Med. Gaz. of Nantes*, the following combination is of service in the treatment of chronic bronchitis of elderly individuals:

℞. Essentiæ anise	gr. xv	1
Aq. ammoniæ	gr. lxxv	5
Alcoholis (90 per cent.)	3vi	25

M Sig.: Five to six drops in water or syrup three times a day.

Antisepsis of the Mouth.

The following combinations are recommended by Miller in the *N. Y. and Phila. Jour.* as antiseptics for the mouth:

℞. Acidi thymici	gr. iii		20
Acidi benzoici	gr. xlv	3	
Essent. menthæ pip.	m. x		65
Tinct. eucalypti	3ivss	18	
Alcoholis	3iii	90	

M. Sig.: Put a sufficient amount in the glass of water to render the water milky and use as a mouth wash; or:

℞. Acidi tannici	3iii	12
Menthol	3ii	8
Thymol	gr. xv	1
Tinct. benzoini	3iss	6
Alcoholis	3iii	90

M. Sig.: Ten drops in half a glass of tepid water.

Ulcer of Stomach.

Gustav Fütterer, in *Northwestern Lancet*, states that round ulcers of the stomach are very difficult to heal as long as anemia is present. Consequently he advises the treatment and correction of the anemia present which may be primary in the form of chlorosis or of a secondary character. He recommends that the juice extracted from four pounds of beef be given daily until the hemoglobin is approximately normal. The patient should be put to bed under the care of a nurse. It is not necessary to resort to rectal feeding when the beef juice is given. As soon as the hemoglobin has reached the proper proportions the beef juice may be omitted and the patient placed on a milk diet and at the end of a month or six weeks the patient may get up and begin taking solid food in small quantities at first. He recommends in some of these cases a solution of silver nitrate, grains five to the ounce, giving a tablespoonful on an empty stomach three times a day.

Variations in the Strength of Digitalis Leaves.

From the observations made by Focke, according to an abstract in *Amer. Med.*, the variations in the strength of digitalis leaves which arise in the drug store are connected regularly with the time of year in which the preparations are sold. The leaves in July and August are, according to Focke, four times as strong as those displaced by them. Until the beginning of October they lose half the strength, until January two-thirds, and until summer three-fourths. He demonstrated the comparative strength of the leaves on animals, observing that poisoning took place more frequently and with smaller doses in the second half of the year. Poisoning occurring in the first half was due to very large doses.

Migraine.

J. R. Clemens, in *Med. News*, highly recommends the use of potassium iodid in the treatment of migraine to the exclusion of all other remedies. He observed that the headache in migraine is very similar to that due to cerebral syphilis, being of a deep-seated, constricted character, with nocturnal exacerbations. He gives it in doses ranging from 5 to 15 grains, three times a day. By this treatment he noticed that the headaches diminished both in frequency and severity.

The following combinations are of value in the treatment of migraine according to Yeo in his *Clin. Ther.:*

℞. Sodii salicylatis	gr. xlv	3
Sacch. lactis	gr. xxx	2

M. Ft. chart, No. vi. Sig.: One powder to be taken every hour at the time of the attack; or:

℞. Caffeinæ citratæ	gr. xv	1	
Quin. bisulph.	gr. xxii	1	50
Sacch. albi	gr. xxx	2	
Olei menth. pip.	gtt. i		06

M. Ft. chart. No. x. Sig.: One powder to be taken three times a day; or:

℞. Antipyrini	3iss	6
Pot. bromidi	3iv	15
Spts. chloroformi	3ii	8
Aquæ camphoræ q. s.	viii	240

M. Sig.: One large tablespoonful to be taken when the attack comes on and a dessertspoonful night and morning between the attacks.

As an aperient in migraine the following:

℞. Quininæ sulph.	gr. xv-xxx	1-2
Ext. aloes aqueous	gr. lxxv	5
Pulv. ext. glycyrrhizæ q. s.		

M. Ft. pil. No. lx. Sig.: Two pills to be taken night and morning.

Opium Habit.

In an abstract in the *N. Y. and Phila. Med. Jour.* occurs an outline of treatment of the opium habit, as carried out successfully by Dr. E. I. Osgood in breaking up the opium habit among the Chinese. He gave four pills daily of one of the following combinations originated by Drs. Macklin and Beebe:

℞. Quininæ sulph.	gr. ss-2/3	03-.04
Ext. cannabis ind.	gr. ss	03
Ext. nucis vom.	gr. 1/3-ss	02-.03
Sod. phosphatis	gr. 2/3	04

M. Ft. pil. No. i. Sig.: One such pill four times a day; or:

℞. Quininæ sulph.	gr. ii	12
Ext. bellad.	gr. 1/6	01
Ext. nucis vom.	gr. 1/6	01
Ext. cannabis ind.	gr. 1/4	015

M. Ft. pil. No. i. Sig.: One such pill four times a day.

Acne and Rosacea.

Dr. T. G. Lusk, in the *Post-Graduate*, states that the first thing to be considered in the treatment of acne and rosacea is

careful regulation of the diet: The withdrawal of such articles as cake, ice cream, pickles, nuts, oatmeal, pastry, greasy foods, such as goose, pork and duck; fried foods, sausages, salt meats, cabbage, cauliflower, turnips; alcoholic liquors in any form; tea and coffee must be taken in limited quantities. The diet, in other words, must consist of wholesome food, properly prepared and thoroughly masticated and the meals taken at regular intervals. The general hygiene of the patient must be carefully inquired into. The bowels should be properly regulated and tonics of iron, arsenic, strychnin and quinin given internally.

Locally, thick oily skins should receive vigorous treatment with the application of tincture of green soap, after which the following ointment should be applied:

℞. Sodii boratis 3ii 8
Ung. aquæ rosæ .....℥i 30
M. Ft. unguentum. Sig.: Apply locally.

By first scraping the face with a sharp-ringed curette the removal of the blackheads is rendered easier by means of proper instruments.

The following antiseptic and stimulating lotion is of value in relieving the condition:

℞. Zinci sulph.
Potass. sulphuret.
Sulphuris precip., āā.....3i 4
Alcoholis q. s.
Aquæ rosæ q. s. ad .....℥iv 120
M. The zinc and potassium sulphuret are each to be dissolved separately in one half the quantity of rose water and then slowly combined with constant stirring; add a sufficient amount of the alcohol to the sulphur to make a thin paste and add to the solution. Sig.: Shake the bottle, and apply thoroughly to the face twice a day.

The following is weaker and may be substituted for the foregoing:

℞. Sulphuris precip.
Tinct. camphoræ, āā.....3i-3ii 4.-8
Spts. etheris.....3iv 15
Alcoholis q. s. ad.....℥iv 120
M. Ft. lotio. Sig.: To be applied twice daily.

The author prefers lotions to ointments for local purposes.

Deep-seated abscesses must be evacuated by incising with a small bistoury, and after expressing out the contents apply pure carbolic acid on a toothpick, and follow this by an application of the foregoing zinc and sulphur lotion.

For deeply-seated nodules the following is of great value:

℞. Potass. carb.
Sulphuris precip.
Glycerini, āā.....3ii 8
M. Sig.: Apply locally only over the nodules. It should never be used on delicate skins. In most cases the application of this ointment renders incision unnecessary.

In the second stage of acne vulgaris after the lesions have been infected by the finger-nails, Sheffield recommends the following lotion:

℞. Sulphuris precip. 3i-3ii 4.-8
Pulv. camphoræ .....gr. x 65
Pulv. tragacanthæ .....gr. xx 1 30
Alcoholis 3ii 8
Aquæ rosæ .....℥i 30
Aquæ calcis q. s. ad 3ii 60
M. Sig.: To be applied externally two hours before retiring and washed off the next morning with hot water.

In the third stage of the disease, when there is a great deal of nodular induration, the following is recommended internally:

℞. Pot. iodidi
Sodii bicarb., āā .....gr. v 30
M. Ft. capsula No. i. Sig.: One such dose once or twice daily until active pustulation occurs, when it should be discontinued.

The lesions in rosacea, according to Lusk, consist of erythema, inflammatory papules and pustules with dilated superficial blood vessels. The inflammation is more diffuse than in acne. The internal treatment of rosacea is practically the same as of acne, except that the mineral acids and bitter tonics are more especially indicated in the former. The zinc and sulphur combination is indicated locally.

In the destruction of the dilated vessels, electrolysis is of greatest benefit. This may be carried out by applying the needle attached to the negative electrode of the battery, and employing a strength of 6 to 10 milliamperes.

Medicolegal.

Liability of Town for Care of Smallpox Patients.—In the case of People vs. Eno and others, brought on the relation of a practicing physician to review the action of a town board on a claim of his, the Fourth Appellate Division of the Supreme Court of New York says that the board of health of the town is a local agency, created by statute for the express purpose of preserving the health of the residents of the town. When so virulent and dangerous a disease as smallpox developed within the limits of its jurisdiction, it was its undoubted duty to take immediate and efficient steps not only to furnish care and attendance to persons afflicted with the disease, but to protect, as far as possible, the residents of the town from the danger to which they were exposed by reason of its contagious and malignant character. To this end it was authorized to incur any reasonable expense, and the expense thus incurred by express direction of the statute became a charge on the town, which was to be audited, levied, collected and paid in the same manner as are other legal charges. It is clear, therefore, the court goes on to say, that, if this physician was employed by the health board, or by any other duly authorized party acting in its behalf, he should be allowed a reasonable sum for the services rendered by him in virtue of such employment. He alleged in his petition that he was thus employed on the 29th day of April by the health officer of the town, and in this he was corroborated by one of the members of the board of health, who stated unqualifiedly that the health officer was authorized by the board to employ the physician, and that he did employ him, and gave him the assurance that he would be well paid for his services. There was also further corroboration of this allegation in the affidavit of a third party, who said that the health physician stated to this physician in his presence that the town board of health had authorized the physician to treat and care for all patients who then had or might thereafter be afflicted with the smallpox, and would pay the reasonable value of his services for such care and treatment. But it seems that, on May 7, in order, as he said, that he might have some definite understanding as to his compensation, the physician sent a letter to the health board, informing it that he would be unable to longer continue his services in connection with the smallpox patients without receiving as his compensation therefor the sum of $10 per day, and that on May 9 the town board of health met and passed a resolution employing him at the rate named in his letter. Under these circumstances the court holds that the town board was not justified in rejecting the physician's claim for charges prior to May 9, but, it being practically conceded that his charge for his services was, under all the circumstances, a reasonable one, he should be allowed for the full amount thereof.

Physical Examination Requiring Rupture of Hymen.—The Court of Appeals of Kentucky says, in Louisville Railway Company vs. Hartlege, that, from a review of the cases in which the question of ordering a physical examination of the party seeking to recover for personal injuries has been before it within the last few years, it appears that the weight of authority favors the right of the party sued to demand a physical examination of the party suing. The decisions, however, recognize that the party sued has no absolute right to have an order made to that end, but that a motion therefor is directed to the sound discretion of the court, and that its exercise will be reviewed on appeal, and corrected in case of abuse; that such an examination may be ordered when the

facts can only be brought to light or fully elucidated in that way, and when it can be made without danger to the life or health of the party suing, or without the infliction of severe pain or offending decency. In this case, two physicians made affidavit that the injury to the party by whom the action was brought could not be objectively determined by an examination of her person, except by exploring the vagina and breaking the hymen, which was intact; that her injuries were to be determined by her clinical history and symptoms alone. In another affidavit they stated that a physical examination could not be made without injury to the party, and would cause her pain, and could not be made without the exposure of her person. The substance of the evidence with regard to her injuries, alleged to have been caused by her being thrown against a seat on the floor of a street car, was that she suffered pain in her side and hip from the time of the injury until the trial; that about a week after the injury she was compelled to go to bed on account of the same, and there remained for two weeks or more, under the treatment of a physician; that previous to her injury she had been in perfect health; that from and after the time she received her injuries to the time of the trial her menstruation periods had been prolonged from two to four or five days, which detained her from her work; that the flow was much greater and painful; and that she had not been troubled with it prior to the injury. Other lady witnesses corroborated her in these statements. The two physicians referred to, as well as two surgeons representing the company, were present, and heard all the testimony with reference to her injuries, and the probable effects therefrom. They testified—the two for her from their examination, and from the clinical history of the case as detailed by the witnesses—that this trouble with her menstruation was probably caused by the injuries received. The other two said that it could not have been so caused or produced. The court says that the record disclosed the fact that the extent of her injuries were substantially disclosed by the means used, and that the drastic measures demanded by the company were unnecessary to that end. The small verdict in this case ($500) was one evidence of that fact. And the court declares that it does not feel authorized, nor does it deem it proper, to reverse the case and order another trial, and have the party's person exposed, suffering humiliation and the loss of the evidence of her virginity, to relieve the company of so small a verdict obtained under the circumstances shown in this record.

Employment of Physician on Board—Duty of Chairman.—The Supreme Court of Minnesota holds, appeal of board of health of village of Buffalo Lake, that a town or village board of health, formed under the provisions of the general statutes, one of whose members is a practicing physician and surgeon, may employ such physician to act for the board in all matters requiring such services. It says that the law requires that one member of every board of health shall be a practicing physician and surgeon, and this requirement was not without purpose. The object of the legislature in incorporating this provision into the law is obvious. It was clearly for the purpose of providing the board with a person competent to treat diseases of a contagious character, and there can be no doubt that it contemplated his employment in all cases where professional services of the kind are necessary. If this were not so the provision requiring a physician to be on the board would be of no purpose or effect. The general rule which prohibits a member of a board or council from employing or contracting with one of the members thereof does not therefore apply. Besides, whether the physician employed by a board of health, under such circumstances as here involved, where the chairman of the board was a physician and was employed by the board to render professional services to smallpox patients under quarantine, is to be compensated for his services from the public treasury, and to what extent, is a question to be determined by the county board of county commissioners, and the local board has no voice or power to act in that behalf. Hence one of the strongest and the principal reason for the prohibitory rule in such cases is absent. But the chairman of a town or village board of health is authorized by Chapter 238, page 378, of the general laws of Minnesota of 1901, in his official name and capacity to present an itemized statement of all expenses incurred by the board in the matter of quarantining persons affected with contagious diseases to the board of county commissioners for allowance, and to conduct all proceedings to enforce payment of the same. When an appeal is taken from the action of the county commissioners to the district court, judgment, the Supreme Court holds, may be awarded in his name as such official, and in cases where the county board disallows the claim, and judgment is obtained in the district court against the county, he must necessarily act as a disbursing officer. Nor does the court consider the situation in any way changed in this case by the fact that the village in which the smallpox patients referred to were quarantined, though under no legal obligation to do so, voluntarily paid to the various persons entitled thereto the amounts due them according to the statement of the chairman of the board of health, it not appearing that such payment was made or received in discharge of the indebtedness. In other words, the court holds that its action in that respect did not release the county. If by such payment the village became entitled to reimbursement, the recovery by and in the name of the chairman of the board of health placed him, as to the judgment or proceeds collected therefrom, in the position of a trustee, and he might be compelled to account to it. The expenses involved in this action having been incurred by the village board of health, in quarantining certain smallpox patients, partly prior and partly subsequent to the passage of the statute above mentioned, the court holds that, under the provisions of that statute, the whole expense was a proper charge against the county. It says that the expense incurred in controlling contagious diseases and preventing their spread among the people is one of a public nature, and properly made, in cases where the persons infected with such disease are paupers and dependent on charity for support, a public charge. The mere fact that the legislature saw fit and proper to shift the burden from the town, village or city to the county would not warrant a division of the expenses incurred, in a continuing case, partly before and partly subsequent to such change in the law.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

New York Medical Journal.

August 8.

1 *The Influence of the Roentgen Ray on Sarcoma: Further Observations. William Coley.
2 *Influence of Altitude on Heart Disease: Some Further Remarks and Queries. Robert H. Babcock.
3 *The Psychical Relations of Tuberculosis in Fact and Fiction. (Concluded.) G. A. De Santos Saxe.
4 *The Cause and Specific Treatment of Hay Fever: A Preliminary Report on the Uses of the Toxins and Antitoxins of Professor Dunbar. Emil Mayer.
4½ Malta Fever. C. F. Mason.
5 *Peripheral Paisies Following Manual Replacements of the Congenitally Dislocated Hip. Henry L. Taylor.
6 Rheumatism and Typhoid in Childhood. J. R. Clemens.

1. **Sarcoma and the X-Ray.**—Coley has treated altogether some 30 cases of non-operable sarcoma, which he analyzes, and some of which he reports. He thinks the influence of the *x*-ray is much more marked on this class of malignant tumors than in carcinoma. From personal experience and study of the literature, he does not believe we are justified in using the method in any save inoperable cases. An exception to this rule might possibly be made in sarcoma of the extremity where amputation was the alternative. He believes that in such cases a brief course of the combined *x*-ray and toxin treatment might be justifiable. We have proven thus far that the *x*-rays have a decided inhibitory action on the various forms of sarcoma; in some cases sufficient to cause their entire disappearance, but there is a strong tendency, nevertheless, to local or general recurrence and not enough time has elapsed to warrant a complete cure. Good results can not be expected without prolonged treatment.

2. **Altitude and Heart Disease.**—Babcock reports some peculiar and rather contradictory cases of effects of altitude on cardiac patients, and he asks if we are to seek the explanation of the ability of one patient and the inability of another to endure altitude in the conditions of the blood pressure, or shall we conclude with Regnard that anyone can reside at an altitude of a mile or so after he has become acclimated. He thinks if Colorado physicians would make it a rule to record the blood pressure in newcomers, especially in those showing signs of cardiac dangers, and compare them with the blood pressure of the same persons after accustomation to the altitude, the results would be of value. Consumptives have generally a low tension pulse and yet most of them are able to bear residence in Colorado without serious cardiac embarrassment. He suggests it as his growing belief that if a cardiopath will remain inactive at a high altitude until he is accustomed to the change, he can visit the mountains with impunity. The dangers of travel and residence at high altitudes seem to be greater with the normal individual, who is likely to overdo. The heart becomes more easily overtaxed.

3. **Tuberculosis.**—Saxe's article is concluded in this issue. He discusses the effects of tuberculosis on insanity and quotes from Fanoni as to the criminal tendencies of the consumptives. His summary and conclusions are given as follows:

1. The consumptive exhibits in the average case, traits of mind and of temperament that have been made use of by some of the best writers of fiction in describing the characters of tuberculous persons—traits that are well worth studying, inasmuch as they are directly connected with the disease, although not specifically characteristic of tuberculosis.
2. The psychical and temperamental traits of the average consumptive have not been studied by medical men with the attention which they deserve.
3. The only probable theory thus far advanced as to the causes of the mental and moral degeneration of the consumptive, leading even to criminal tendencies, is that of toxic poisoning of the central nervous system by the products of the tubercle bacillus, resulting in neurasthenia, psychasthenia, hysteria and insanity.
4. The fundamental factors in the psychical make-up of the typical consumptive are the loss of self-control, the rise of brute selfishness, the increase of susceptibility to suggestion, to emotion and to nervous irritation, and the tendency to rapid, nervous and psychical fatigue.
5. There is no tangible proof that the sexual functions are exalted in tuberculosis, but in all probability the sexual irritability is raised in the early stages of the disease and lowered coincidently with the lowering of vitality in the later stages.
6. In all probability there is a connection between tuberculosis and insanity, the tuberculous toxin contributing, with other factors, in persons rendered susceptible by psychical and somatic degeneration, to the derangement of the mind. Any form of insanity may be found in tuberculous persons, and the term "tuberculous insanity" should not be used to designate a type of insanity peculiar to tuberculosis.
7. The criminal tendencies of consumptives have been observed with sufficient frequency to justify an investigation into the medico-legal question of restricting the responsibility of a criminal on the ground that he is tuberculous. Mental and physical degeneration, together with the tuberculous intoxication already referred to, are the chief factors in the make-up of the tuberculous criminal.
8. The euthanasia of consumptives, which has excited speculation, is to be explained on purely physical grounds, the changes in the nervous system being so marked at the time of approaching dissolution as to efface the patient's suffering and render his death easy.

4. **Hay Fever.**—May has experimented with Dunbar's antitoxin and finds it effective on the spring form of hay fever in this country, as well as in Germany. He thinks that the conclusion of Dunbar that spring hay fever is due to the pollen of grasses is supported, and reports his suggestion that the autumnal cases will possibly find a toxin to which they will also respond.

5. **Congenital Hip Dislocation Paralysis.**—Taylor has observed several cases of paralysis of the quadriceps following reposition of congenital hip dislocation, an observation which has also been made by Lorenz. This condition is easily overlooked, and he thinks that possibly it is more common than has been estimated. The prognosis is generally good. Certain forms of peroneal and sciatic palsies, however, of which he has observed cases, may cause more or less trouble. He thinks that the manipulation of reposition should be deliberate and careful, and when serious obstacles to reposition exist, manual force alone should be abandoned.

7 *The Sources, Favoring Conditions and Prophylaxis of Malaria in Temperate Climates, with Special Reference to Massachusetts. (Concluded.) Theobald Smith.
8 The Element of Torsion in Lateral Curvature of the Spine; Its Place in the Cause and Treatment. Robert W. Lovett.
9 A Criticism of Klemperer's Work on the Condition of Uric Acid in the Urine. Francis H. McCrudden.

7. **Malaria.**—Smith concludes the subject, which was discussed in two previous numbers, with the following summary:

1. There is no evidence that any but the tertian form of malarial fever can be propagated in Massachusetts.
2. The original source of tertian infection must be looked for in the blood of individuals coming from permanently infected localities in our own country and in southern Europe.
3. There is no definite information as to the stage of disease or relative immunity in which mosquitoes may become infected, but analogy with similar diseases of animal life indicate that the gametes are not formed early in the disease, and that relatively immune persons are the most dangerous, especially after fresh exposure, because in them gametes form very promptly without causing much or any clinical disturbance.
4. The dissemination of infection is most easily promoted in our latitude when people live in a crowded condition, unprotected from mosquitoes and near breeding places of anopheles.
5. The decline and disappearance of malaria after importation and epidemic prevalence is in part due to relative isolation of the inhabitants and protection by quinin and from mosquitoes, and in part to the absence of persons partially immunized by long exposure in endemic localities.
6. There is some evidence that sewage pollution in surface waters favors mosquito larvæ directly, through increase in food supply; indirectly, by injuring their enemies.
7. Since malaria may be latent and, hence, unrecognized, and since it is largely a disease of the lower classes, whose movements it is difficult to control, the best method of reaching it is to suppress the mosquitoes whenever possible.
8. Malaria is of sufficient importance to become a notifiable disease.
9. Infants and children exposed should have their blood examined during any disturbance of health.
10. In times of epidemic malaria it may become necessary to make special regulations governing infected persons.
11. It is of great importance that the relation of the widely distributed species, *A. punctipennis,* to the parasite of tertian fever be accurately determined.
12. It is also highly desirable to test the infecting power of fresh cases of tertian fever as compared with relapses and with individuals from malarial countries.

14 Resection of the Left Pelvis for Osteosarcoma. M. Stamm.
15 The Palliative Treatment of Fibroid Tumors of the Uterus. Augustin H. Goelet.

10. **Acute Non-Suppurative Encephalitis.**—The case here reported by Brooks was one of a girl 19 years of age, without prior bad habits or bad personal or family history, except excessive tea drinking and possibly drug taking for headaches. The postmortem is detailed. There was reflex cerebrospinal meningitis, probably secondary to cerebritis and of the cellular type, as described by Delafield and Prudden. There was also a general non-septic cerebritis of all parts of the cerebrum, most marked in the cortical and motor region with resulting degeneration of the nerve fibers extending into the spinal cord and through the internal capsule, which have their origin in the involved portions of the cortex. There was also an inflammation of the cerebellar tissues in a less marked degree, and slight, probably secondary degeneration of the ganglion cells of the anterior horns. As to the origin of the disease nothing is explained, but he thinks the cause was not infectious. The best way to explain it, he thinks, is by toxins which may have been of bacterial origin, since such conditions are found to follow influenza, but it may have been due to metabolic origin or to the toxic action of drugs. The patient had been in the habit of taking headache powders, and it is possible that these might have caused the disorder, though he does not know of these symptoms being produced by such drugs. The symptoms are such that the cases are probably sometimes misunderstood or credited to hysteria.

11. **The Form of the Ureter.**—Robinson illustrates the various types of ureters, showing the swellings and contractions, which he calls pelvic spindles and isthmuses. Of these the right lumbar spindle is generally larger in women than in men.

12. **Malaria.**—Wood has found the method described below especially valuable in the staining of fresh specimens for the malaria organism:

Fix the preparation for one minute in strong methyl alcohol, wash off in water and stain the slide for a few seconds with a 0.1 per cent. aqueous solution of yellowish eosin. The surplus of the eosin solution should be poured off and a few drops of a 0.2 per cent. solution of methylene azure poured over the slide. The staining will be complete in from one-half to one minute and the slide may be washed with distilled or tap water and dried with blotting paper. . . .

A longer treatment with the azure solution produces a deeper chromatin stain, a shorter treatment produces a stain of less intensity. If a stain of any particular depth is required the whole process may be easily observed under the microscope, selecting a group of leucocytes as a guide. The stain will be seen to gradually color the nuclei of the polynuclears a deep red, and at the proper point the neutrophile granules will be easily visible with a good four mm. dry lens. At the same time the nuclei of the large and small lymphocytes assume a deep red color and the cell bodies of the large forms color a pale blue, while the bodies of the small cells will be a deep blue. At this stage of the process the malarial parasite is of a pale blue color, with deeply red chromatin granules. If the methylene azure has remained in contact with the smear but a short time the red cells will be of a bright pink color, but if the staining is prolonged the red cells become bluish or greenish in color. After prolonged staining with the azure the color of the neutrophile granules generally fades and the bright pink of the eosinophiles is replaced by a bluish tint. For general purposes, therefore, it is best not to stain the slide too long with the methylene azure. . . .

Beginners may mistake the blood plates, which often lie in depressions in the red cells, for malarial parasites, especially as they stain red with the chromatin dyes. The distinction must be made by the differences in morphology. The blood plate is not sharply outlined and the nuclear substance is in the form of an indistinct mass not surrounded by a clear zone, while the small ring-form of the malarial parasite is very sharp in its outline, as is also the chromatic substance, the latter being surrounded by a clear zone and beyond this by the blue ring of the body of the parasite.

He has also been able to make good stains on old slides with this eosin and methylene-blue mixture.

13. **Prostatic Obstruction.**—Chetwood, from his experience in 45 cases, concludes that prostatotomy is less dangerous than prostatectomy. It is the operation of choice in a large number of cases of obstruction, notably those of moderate glandular enlargement or orificial hypertrophy and contracture in which the prime object is removal of the obstruction and depression of the bladder orifice. He also finds that galvano-caustic incisions when combined with perineal cystotomy accomplish satisfactorily the desired result, shorten the operation and minimize the dangers.

22 The Ill Health of Jane Welsh Carlyle. George M. Gould.

16. **Acute Rheumatism.**—McCrae reports and analyzes the experience at the Johns Hopkins Hospital during the past year, covering some thirty-seven cases in forty admissions. The chief points noted are the severer type of the disease observed over that of previous experience, the greater proportion of cardiac complications, the long duration of the disease and the mortality. The cultures that were taken were practically negative throughout; the series, therefore, throw no light on the bacterial cause of the disorder. Of the 37 cases, 4 died in the hospital, or 11 per cent., against three deaths out of a total of 270 cases previously treated. The author remarks that the experience of these cases shows that acute rheumatism can kill as well as cripple, and he questions whether the former would not sometimes be the more merciful.

17. **Beri-Beri.**—Currie reports nine cases of what appeared to be beri-beri occurring in Chinamen employed in the Alaskan canning establishments. Four of the nine cases died. He thinks probably 4 per cent. of the Chinamen thus employed were attacked. The vessels which carried them back and forth did no other trading, and, therefore, did not enter into any known beri-beri zone. The cases, therefore, seem indigenous.

28 *Some Dangers of the Hot-Water Bottle as Applied to the Newborn. Douglas H. Stewart.
29 *Artificial Fluorescence of Living Human Tissue. William James Morton.

23. **Milk Examinations.**—Kerley, Gieschen and Myers conclude their article with the following conclusions:

1. Breast milk and cow's milk are both acid.
2. The litmus paper test for milk is unreliable because of the variation in the quality of litmus paper, and the litmus taking part in the reaction and not acting as an indicator.
3. The effect of adding lime water or bicarbonate of sodium to feedings is to retard or inhibit the formation of curds by rennet.
4. The teaching that lime water, bicarbonate of sodium, or carbonate of potassium should be added to fresh milk or feedings simply because they are antacids is erroneous.
5. The addition to milk or feedings of alkalies or salts that become alkaline in solution is an empirical method of aiding digestion by preventing the formation of dense curds that would slowly leave the stomach and be difficult of digestion in the intestine.

24. **Heredity in Eye Diseases.**—Weeks notices the various forms of eye trouble which may be influenced by heredity, including congenital conditions, such as polycoria, epicanthus, coloboma of the iris, aniridia, colobomæ of the choroid, albinism, malformation of the globe, cataract, optic nerve atrophy, retinitis pigmentosa, glaucoma, color blindness, etc. He remarks that the most common causes of eye disease are heredity and syphilis, and enumerates a number of conditions of this latter type.

25. **Trachoma.**—The treatment of trachoma is summed up by Claiborne as medicinal or surgical or a combination of the two. In the non-inflammatory forms characterized by frog-spawn granulations, the operation is expression alone with appropriate after-treatment as indicated. The best instrument, in his opinion, is the Knapp roller forceps or some modification. In the inflammatory form the operation of expression followed by a mild astringent and finally by a copper stick, is indicated as long as granules exist in a reasonable quantity. When the disease has passed the granular and is in the cicatricial stage, copper sulphate alone or in combination is indicated.

26. **Intragastric Electrization.**—Marshall describes his experience with the Einhorn method of intragastric electrization, which he says should not be resorted to except where medicinal and dietetic treatment has failed, but in such cases it will be found of inestimable value.

27. **Intercostal Phonation Phenomenon and the Litten Shadow.**—These phenomena are described by Abrams. The first consists of a distinct elevation of the intracostal space when short words or syllables are uttered by the patient. It is best seen, naturally, in lean individuals, and is best elicited if during phonation the patient closes his nostrils and places the other hand over his mouth so as to partially obstruct the exit of air. Its value is in differentiating lung infiltrations from accumulations in the pleural cavity, but it is not infallible here, as it can not be used in obese patients, when the exudate is compressing the lung, or when pleural thickening and adhesions exist. The Litten shadow is the method of discovering the diaphragm movements. The patient is placed with head and shoulders toward the light, lying on his back, with feet directed toward a window and chest exposed. Cross lights should be eliminated. It can also be shown with a strong light held at the foot of the bed, excluding other lights. The observer stands at the side a few feet from the patient, with his back to the light and observes the lower chest at an angle of 45 degrees. The patient is directed to take deep breaths, and as the ribs rise with each inspiration a short, narrow shadow moves along the axilla from about the seventh to the tenth rib. This is less evident during expiration, and cuts the ribs at an oblique angle. It is best seen in lean individuals of both sexes and is never absent in health, excepting in very fat individuals or those who can not take deep breaths. It permits us to say that in that particular chest region the

diaphragm and lung lie in contact with the thoracic wall and both are freely movable. Its absence would suggest an opposite condition of things, adhesions, emphysema and whatever would displace or make irregular the shadow. He gives a synoptic table of the phrenic shadows in the various conditions where it is diminished, absent or increased. He has tried to exaggerate it by various means and finds if the skin is colored yellow over the area it is much intensified. If nothing else is at hand the use of yellow vaselin will suffice.

28. **Hot-Water Applications to the New-Born.**—Stewart calls attention to the dangers of burning feeble children with hot-water bags, and this accident is not as uncommon as it ought to be. It may frequently be overlooked by the physician, especially if located on the back. He says if the reader will examine every new-born child on the third, sixth and seventh day after birth he will become just as timid as is the writer, and as watchful to see that there is a thick folded blanket above every hot-water bag and a thick folded towel under every ice bag.

29. **Human Tissue Fluorescence.**—Morton finds that administering quinin renders the tissues fluorescent and suggests that it might possibly be of value in cancer cases. Acting on this idea he has, during the last year, been in the habit of administering from 5 to 10 gr. or more of quinin bisulphate about one hour before *x*-ray treatment. While he can not positively affirm it, he believes that the cases thus treated by the combination of fluorescing medicines and the *x*-ray have made more improvement and more certain recoveries than patients not thus treated. He thinks this method, which he calls the *x*-ray histofluorescence, is worthy of trial. He has also used it in some other forms of disease, such as chronic malaria, Hodgkin's disease, lupus, tuberculosis and tuberculous deposits. He has shown the existence of this fluorescence by photographs of portions of the human body treated with quinin either applied locally or hypodermically in a dark room by its own light.

43 Teratoma of the Ear. William C. Braislin.

39. **Hematemesis Following Appendicectomy.**—Fowler reports a case of fatal hematemesis in an otherwise apparently healthy individual after appendicectomy. Minute ulcerations were found in the stomach, mainly on the lesser curvature. The processes were apparently quite recent, as shown by microscopic examinations, and he thinks that the multiple foci had their origin without doubt in the gangrenous appendix. The toxicity of the appendiceal lesion is responsible for the fatal issue in such cases. The question is whether the emboli bearing staphylococci pass through the pulmonary circulation, and finally find lodgment in the vessels of the gastric mucosa or whether the staphylococci alone were transported to and produced thrombi with subsequent embolism in the vessels. The latter view is sustained by two facts: In one section there was a focus of necrotic tissue containing staphylococci, and the vessels of the submucosa near this area contain recent thrombi, and in another section an exquisite embolus was seen involving a vessel in the mucosa near its bifurcation, the vessel and its two branches containing recent blood clot.

40. **Tubal Pregnancy.**—Chase emphasizes the importance of the practitioner examining a woman liable to pregnancy, bearing in mind the possibility of this condition. In case it occurs and rupture has not taken place the sooner the pregnant tube can be recognized and removed the better. In the cases in which the condition points to recent rupture of the intraperitoneal variety and evidences of hemorrhage are present, immediate operation should be done. It is criminal to leave a woman to chance in such cases. If evidence is present that the rupture is extraperitoneal—into the broad ligament—and the resulting hematoma is moderate in size, waiting for developments may be justified, as nature may possibly take care of the mass. Finally, while it will continue to happen that ectopic pregnancy will show a frightful mortality where no accurate diagnosis has not been made until too late, it is true that with a proper appreciation of the grounds, on which at least a presumptive diagnosis can be made by the practitioner, an increasing number of lives can be saved.

41. **Skin Infection.**—Fowler insists on the importance of skin infection, and gives his own methods. He trims his finger nails as closely as possible consistent with their aid in the tactile sense, and then washes with tincture of green soap and warm water. The spaces between the nails are then scraped with a blunt instrument to loosen the dirt beneath the nails, which has been previously softened by the washing, following this with a special nail brush, consisting of small wire brush stretched in a frame, such as are sold in lengths as smoking pipe cleaners. Then follows the ordinary hand brush properly sterilized, scrubbing the palms, ends of the fingers, including the entire nail. The backs of hands, where eczematous conditions are apt to arise, and the arms as well are cleansed with a folded square of gauze used as a wash cloth. Lukewarm running water is used. All traces of soap are now washed off with a lukewarn 1 to 2,000 mercuric chlorid solution, after which an alcoholic solution of the same strength is used. With the aid of gauze the alcohol is rubbed in and about the matrix of each nail separately. If the hands have been recently exposed to any special infection, such as a pus case, additional precautions must be taken. They should be thoroughly and deeply stained with permanganate and corrosive sublimate solution. A two minutes' immersion is sufficient to stain the hands deeply, after which he decolorizes in a hot saturated solution of oxalic acid. The addition of half an ounce of strong ammonia water to a quart of sterile water makes a solution which will neutralize the acid, after which the ammonia solution is washed off in the bichlorid solution. The hands are again stained in potassium permanganate and mercuric chlorid solution and this stain permitted to remain. During the operation it is of utmost importance, he says, to dip the hands at least every five minutes in cold solution of sublimate. In septic cases bleaching in oxalic acid before the operation is omitted, the hands being simply protected by deeply staining them with permanganate and sublimate solution and permitting this to remain during the operation. This course is also followed in clean cases when the hands have not been recently exposed to a special infection. The stain serves the purpose of preventing the passage of micro-organisms from the depths of the skin of the hands to the surface. The principal points are summarized as follows: 1. The necessity of cleansing the surface and all accessible harboring places for dirt. 2. The necessity for avoiding irritations to the skin of every description and removing those influences which relax its structure and favor the migration of micro-organisms. 3. The protection of the hands from micro-organisms which give rise to suppuration. 4. Frequent disinfection of the surface of the hands during operation. Fowler has little faith in rubber gloves or impermeable applications to the hands.

44. **Pelvic Deformity.**—Kerr reviews the methods of examining for pelvic deformity, giving his own. In certain cases where the difference in size between the head and pelvis is only slight, a decision should be come to only after watching the progress of the labor, especially in primiparæ. What he calls medium degrees of pelvic deformity are "those cases where the C. V. is round about three inches and there are several alternative treatments, forceps, version, induction of premature labor, symphysiotomy and occasionally cesarean section or craniotomy." The factors that should guide us in the decision are: The stage in which the case is seen, whether during pregnancy or after the commencement of labor, the general condition of the mother, the presence or absence of complications, nature of the presentation, and the possibility of rectifying it if abnormal, the condition of the fetal head, the presence or absence of any complications such as malformations, prolapse of the cord or a plural pregnancy. He has never seen a spontaneous birth occur with a C. V. below 3½ inches. Symphysiotomy should be employed only in judiciously chosen cases, though justifiable in such, and is contraindicated in overlapping of the head at the symphysis more than of the slightest degree. With a vera below 3 inches it becomes a last resort, and 2¾ inches is the lowest limit. With 3 inches, however, a good result can be obtained unless the head is too large. With 3¼ inches he would always try forceps first. He thinks the operation should not be performed in persistent breech presentation, and if the fetal heart beat is unsatisfactory. The induction of premature labor would be an ideal operation if the patient were seen early enough in pregnancy, which is not always possible. If we can be sure of the age, it is undesirable to induce before the thirty-fourth week. Craniotomy is justifiable if the child is dead or the fetal heart is feeble and if the patient has been in labor long before coming under care, and there is a probability of her being already infected; even if the child is alive, he thinks craniotomy is the only alternative if one fails to deliver with forceps. It is absurd to say that it is a crime to perforate a living child. It is occasionally quite sound treatment.

45. **Accouchement Force.**—While every case should be studied by itself, the choice of a method where delivery has to be forced is, according to Dickinson, as follows:

For induction in the latter months and for inertia during labor (other causes being eliminated, such as exhaustion, over-distension and malposition of passage or passenger), the bag comes first, then the hand, and the forceps finish their work. For placenta previa, the balloon for the narrow cervix that bleeds when the head will not plug it and, in bad cases, version, since the thigh is the surest tampon. For brisk hemorrhage of detachment of a normally located placenta, the greatest speed, manual or metal dilatation. For the rigid cervix of the early months and the unyielding girdle of the primipara or the gristly hardness of eclampsia, the powerful Bossi instrument is a great boon, and none of its imitators approach it.

He asks for a careful study of the various methods lest the European enthusiasm for the branched dilator go beyond bounds.

46. **Cesarean Section.**—The indications for cesarean section are noticed by Webster, and the technic described. It is advisable in some rare cases of eclampsia or when the eclamptic dies, the fetus being still alive, but its routine practice is unjustifiable. Vaginal cesarean section is to be recommended in cases of eclampsia in pregnancy or in early labor in which the cervix is rigid and difficult to dilate. It is in such conditions a safer and more scientific procedure than Dührssen's incisions or forcible stretching with metal dilators, as it produces a clean incision in the mesial plane of the cervix and lower uterine segment, hemorrhage from which may be readily controlled. In placenta previa abdominal cesarean section was first advised by Lawson Tait, but Webster considers it rarely indicated, and only when some condition exists rendering the ordinary methods hazardous or impossible. In accidental hemorrhage or placental detachment it has been rarely employed and should be considered only when impossible to carry out the other procedures by the vaginal route. Vaginal cesarean section is indicated in cases of accidental hemorrhage with a critical condition of the patient, and it is impossible to rapidly dilate the cervix by the ordinary means, provided a competent operator is at hand. Also in affections of the heart, lungs, kidneys, etc., where the mother is in danger, and rapid delivery is indicated, the vaginal method is preferable. Abdominal operation should not be employed except where the other is impossible. In case of the mother *in articulo mortis* carrying a viable fetus, or after the death of the mother, it should be the duty of the physician to advise immediate cesarean section in the hope of saving the child The abdominal operation is the easiest and quickest in such cases.

47. **Cervical Incisions in Labor.**—The following are the conclusions of Holmes' article in regard to Dührssen's operation:

1. The contributions of Dührssen to the subject of cervical incisions are not sufficiently original to warrant a proprietary right in the nomenclature: Coutouly, Baudelocque, Bedford, Braun and Skutsch did much to develop our knowledge of the subject. 2. Effacement of the cervix is an indispensable prerequisite to the use of incisions. For this reason incisions are especially applicable to primiparæ and often are contraindicated in multiparæ. 3. Incisions are indisputably of value, even necessary in essential indications. In contributory indications their use is a moot question: the judgment of the operator must decide in individual cases. 4. Manual dilatation preliminary to incisions does not secure the best cervical condition for incisions. 5. Incisions always are potentially dangerous; dangers comprise infection, hemorrhage and extensive lacerations beyond the vaginal vault. 6. Use of incisions demands an obstetric armamentarium, assistants and a definite experience in obstetric procedures. 7. The details of the technic may be modified to suit the taste of the operator. 8. The minimum number of incisions to meet the exigencies of the case should be made. 9. Oblique incisions may be proven to be more advantageous as regards the after effects than the usual quadrant cuts. 10. In the absence of hemorrhage or accessory lacerations, it is a moot question whether the incisions should be sewed up or not. 11. Immediate delivery should follow the incisions.

48. **Bossi Dilators.**—De Lee's opinion, based on three cases and the study of many reported cases, is that there is a small field of usefulness for the Bossi dilator where rapid dilatation of the cervix is necessary after effacement. Before effacement, the colpeurynter should be used. It will be more successful in multiparæ. The dilator will also be useful in dilating the cervix where manual dilatation would be successful. It is more aseptic and the operation is not tiring. The instrument is not safe, but requires careful and skilled watchfulness, and one must search for and be ready to repair more or less extensive lacerations. These are greater in primiparæ. It should never be used in placenta previa. It does not replace the colpeurynter, the use of the hand or cervix incisions in all cases.

49. **Toxemia of Pregnancy.**—Norris thinks that some cases of sudden death after labor can be explained by an unrecognized toxemia originating during pregnancy and suddenly declaring itself by what he has termed a cardiac eclampsia, overwhelming the heart.

52. **Ectopic Gestation.**—Bovée has changed his opinion as to the availability of the vaginal route in operations for tubal pregnancy. His reasons for preferring the abdominal route are given as follows:

1. The field of hemorrhage can be more quickly reached by this route, taking into consideration the relative amount of time consumed in cleansing the two routes under anesthesia. 2. The condition can be the more readily treated and the ligation of blood vessels more readily and certainly performed. 3. The danger from

secondary hemorrhage in ectopic pregnancy is markedly less when ligation is practiced than when removal of blood clots alone is practiced. 4. Any other important pathologic lesion requiring attention in suitable cases may be treated at the same sitting. 5. The shock, as a rule, will be less than if the vaginal incision and abdominal incision are both made. 6. The tube can be more readily removed than by the vaginal route. 7. The abdominal route is applicable in all stages of the pregnancy, while the vaginal can not be employed for the later stages. 8. The vaginal incision has no place in the treatment of unruptured tubal pregnancy, while the abdominal incision is the route *par excellence*.

53. **Cysts of the Peritoneum.**—The explanation of the cysts here given by Dickson is that they are dilated lymph spaces, and are associated with those diseases of the tube and generative organs which are capable of interfering with the free circulation of lymph in the tubal peritoneum.

55. **Placenta Previa.**—After a rapid review of the literature Moran reports briefly five cases of his own observation. He thinks no fixed routine of treatment can be adopted in these cases. There is rarely any difficulty in lateral previa. In the marginal, however, it becomes more dangerous and the central variety is always a matter of grave concern. Hemorrhage and sepsis are the greatest dangers, and rupture of the uterus as a third factor may be added in accouchement forcé, especially when an attempt is made to deliver the child with an insufficiently dilated cervix. Thorough asepsis, rupture of the membrane, partial detachment of the placenta, efficient tampon, dilatation of the cervix with Barnes' or McLean's bag and application of forceps should give good results in the majority of marginal cases. Where version is indicated and there is a possible choice between bi-polar and internal version, the former will be the safer procedure for the general practitioner. As regards cesarean section, he thinks further experience will have to determine the indications, but the statistics are not very encouraging.

59 The Relative Value of Diagnosis. F. C. Gray.
60 *The Treatment of Puerperal Eclampsia, with a Report of Cases. F. S. Clark.

57. **Rheumatism in Children.**—Friedlander notices the characteristics of rheumatism as it occurs in children. He considers that infection is generally through the tonsils. Its clinical manifestations are very different from those in adult life; the arthritic symptoms are not so well marked. Rheumatic purpura is quite common in childhood, and rheumatic nodules occur more often in the rheumatism of children. Another symptom, often of diagnostic import, is recurrent epistaxis for which no cause can be found. While diagnosis in the adult is easy, in children, owing to its atypical course, the symptoms not following in the regular way, and many of the usually prominent ones being absent at times, it may be difficult. The onset of an endocarditis which may be an initial phase of the disease is often very insidious; the continuous fever with slight remissions, though of considerably low degree, not explainable by other definite infection, is one of the most valuable signs of beginning endocarditis we have. We do not have the successive involvement of many joints as in adults. In doubtful cases special attention should be paid to the family history, to the previous history of the patient as regards slight joint stiffness, swelling, so-called growing pains, nose bleed, frequent attacks of tonsillitis, and erythema, and the examination of the heart for signs of endo- or pericarditis and temperature. Rheumatic children do best on a generous dietary with special limitations applied to sugar and starchy foods. Malnutrition is frequently a factor in the cases and milk should be taken in large quantities, plenty of green vegetables and moderate amounts of the more easily assimilated meats. They should wear flannel the year round and avoid exposure to the cold east winds when it is slushy under foot. For actual attacks, the salicylates in combination with bicarbonate of soda are the best treatment. To get good effects the amounts must be rather large. Local applications to the joints are not always necessary. A tendency to frequent recurrence heightens the danger of heart involvement.

60. **Puerperal Eclampsia.**—The treatment of puerperal eclampsia, according to Clark, consists first in the removal of toxins. Failure of the kidneys is our best guide. Mild alkaline waters are our best diuretics. The bowels should be moved freely; phosphate of soda in small doses is an excellent laxative. High injections of saline act by flushing out the bowels. Where the convulsions can not be controlled without terminating labor, the uterus should be emptied. He can not recommend cesarean section. Veratrum viride he finds to be often useful, and calomel in fairly large doses by the mouth and still larger ones by the rectum, is good for controlling convulsions. Chloroform is of value to hold the convulsions in check until other remedies can take effect, but for this purpose it should be used continuously and not intermittently. He reports three cases and insists on the importance of prophylaxis.

66 O'Dwyer Intubation Instruments. Added Small Tubes for Infants Under One Year. Exhibition of Modern Complete Set. W. P. Northrup.

61. **Antipneumococcic Serum in Pneumonia.**—In the eight cases here reported by Morse the effect of the antipneumococcic serum was apparently negative. It seemed to have no effect on the course of the disease or its symptoms.

62. **Infant Feeding.**—Chapin studies the evolution of infant feeding based on the evolution of the species, and discusses the various forms of mammalian life and the developmental life of the fetus. He offers the following, which he thinks are of value:

1. An infant undergoes three stages of development and nutrition: Pre-placental, placental and mammary; and should be looked on as attached to the mother in all three. 2. At the beginning of the mammary stage, an infant has only the rudiment of a true stomach. 3. During the period of mammary development the mother first changes the character of the infant's nourishment from colostrum to milk, and then the infant's digestive secretions so change the character of the milk that, as the digestive juices increase in quantity and strength, the work of digestion is not thereby lessened but, rather, increased, as the stronger the gastric juices become, the tougher the milk curds become, owing to the acid combining with the curds. 4. The milks of all animals will produce good tissue. They differ in composition according to the rate of growth of the young animals. Their proteids differ in accordance with the type of digestive tract they are to develop. 5. No known method of procedure will convert cow's milk into human milk. All methods of artificial feeding must have in view the production of food that will adapt itself to the developing digestive tract. All substances, aside from breast milk, are foreign to the infant's digestive tract, and may at times cause disturbance. 6. In artificial infant feeding, certain minimum quantities of digestible proteid, fat, carbohydrates and mineral matters are needed. The mean composition of breast milk will serve as a general guide to the nutritive requirements of infants. 7. Milk must be the basis of an infant's food, not alone because it contains animal proteid, but because it contains the only available form of proteid that possesses the function of developing the digestive tract. 8. The proteid of cow's milk, which was intended to develop a calf's stomach to digest grass, must be modified or adapted to the infant's stomach. 9. This may be done by chemically or mechanically altering the character of the curds, by diluting milk with either alkalies or gruels. 10. When, for any reason, a sufficient quantity of proteid of cow's milk can not be given, it must be supplemented by other forms of nucleoalbumins until the normal quantity can be digested. It is a gross error to feed too low proteids of milk simply to overcome indigestion.

63. **Recurrent Vomiting of Children.**—In the three cases studied by Pierson of psychic or recurrent vomiting of children, he carefully examined the urine and found diacetic acid present either just preceding or in the early stages of the attack. The treatment used was bicarbonate of soda, given rectally, in quantities up to 100 or 125 grains a day. He thinks there is no question but that the attacks are prevented by this treatment, and that acetone and diacetic acid are present in the urine before or in the very early stages of an attack.

80 Clinical Gonorrhea without the Gonococcus. A. L. Benedict.

70. Neoplasms of the Digestive Organs.—The subject is discussed at length with reference to the leading articles in the literature. The diagnosis is specially noticed, and its difficulties, which are marked in cases where there are no metastases or other palpable evidences of malignancy. In the conclusion of his article Hemmeter treats of the transformation of gastric ulcer into malignant disease. The practical deductions of the histologic diagnosis which can be made from the studies of Hauser, Fütterer and himself, are that it is possible to diagnose carcinoma or ulcer of the stomach histologically by the characteristic behavior of the true muscularis and the muscularis mucosæ and by the fish-hook form of the fissure presented in the outline of the section through the edge of the ulcer nearest the pylorus. By these features he thinks we are justified in concluding that any gastric adenocarcinoma presenting them has been developed on a pre-existing gastric ulcer.

73. Foreign Bodies in the Eye.—Deane describes a method of locating foreign bodies in the eye and reports cases. According to his experience a scleral incision has been in many cases more satisfactory than trying to extract the substance anteriorly with a giant magnet.

74. The Lymphatic System and the Tonsils.—The importance of the tonsils as introducers of infection is discussed by Swain, who reports a case at some length. He thinks the pharyngeal tonsil is the one most frequently attacked in children, and its inflammations are the most likely to endanger the general system. He does not advocate the indiscriminate removal of tonsils. The practical point is, he thinks, when we operate to be thorough in what we do and always remember that we have still some tonsillar tissue left. The patient has still all the chances of being infected. We have not given an immunity because we have operated, we have only given a lessened liability, and should not dismiss the case as needing no further care.

75. Middle Ear Suppuration.—Cases are reported by Potts showing the points of diagnosis. He reviews the symptoms indicating operation in many of the cases, which are given by him in substance as follows:

1. Profuse and long-continued discharge indicating a possible anterior or mastoid involvement and fluctuating swelling over the mastoid, diagnostic when present, but its absence not contraindicating operation. Edema behind the auricle is more apt to be due to furuncle, and tenderness over the mastoid, especially in the region of the antrum, is of great significance whenever present, but may be doubtful or absent if the outer table is much sclerosed. The inflamed, tender and bulging upper and posterior canal wall is one of the most important signs of all, and its non-relief by treatment is a sure indication for operation, as also is a sinus, whatever its location, leading into the mastoid. Facial palsy is of interest but not important. Epileptiform attacks are unusual, but indicate a possible cerebral pressure. Marked and rapid failure in the health is more apt to be found in adults than children. The temperature is more liable to be elevated in children than in adults. Rapid fluctuations of temperature over a range of several degrees is the most important sign of pyemia. Other symptoms are the slow and thready pulse, out of proportion to the elevation of temperature, irregularity or sluggishness of pupils, rapid failure of health and rigors or convulsions, all signs of intracranial pressure. Tenderness and edema over the occipital are very apt to be present when the sinus is thrombosed. Bacteriologic examinations are not positive, but are important.

76. A Xiphosternal Crunching Sound.—This sound, which has not been noticed apparently in many text-books, is described by Solis-Cohen, who reports cases in which it was observed. It is difficult to describe. Before he selected the present designation he called it "friction-sound," "rough rubbing, clicking sound," "brushing sound," "scraping sound," etc. He is inclined to believe that it is due to white patches in the pericardium, and quotes Roberts from Allbutt's System of Medicine, and Gibson, in support of this view.

Archives of Ophthalmology, New York.

July.

81 Aplasia of the Papilla and Retinal Vessels, with a Peculiar Anomaly at the Macula in Eyes Otherwise Normal. Alexander Duane.

89 *The Extirpation of the Lachrymal Sac; Its Indications and Technic. Arnold Knapp.
90 *The Mental Derangement which Is Occasionally Developed in Patients in Eye Hospitals. Charles J. Kipp.

82. Retinal Rosette Formations.—Pusey describes a case analogous to those already described by Murakami of these rosette formations associated with a pure inflammatory process. In the case reported an acute general inflammation of the globe followed an old irritative process. The rods and cones disappeared while the fibrous structures persisted, and even appeared to be increased. In the midst of these changes the rosettes occurred. He accounts for them by holding that they are due to folds in the retina, probably caused by shrinkage of the bands in the vitreous. He thinks they probably have been seen before, but their resemblance to the rosette formations of tumors has not been appreciated.

83. Sympathetic Ophthalmia and Cytotoxins.—Pusey reports experiments to test whether a heterotoxic serum for the eye can be obtained that might account for the phenomena of sympathetic ophthalmia. His results are negative, but they do not disprove the theory that toxic influences are at work in inducing this condition. There are possibly defects in the experiments which render these negative results inconclusive. He is waiting for an opportunity to try an injection of blood serum from the blood of a patient suffering with sympathetic ophthalmia into the blood of a monkey.

85. Neurasthenic Asthenopia.—Gradle describes the condition of asthenopia frequently met with in hysterical and neurasthenic cases in connection with more or less impaired health, anemia, neurasthenic conditions, etc. In a small proportion the discomfort was started in the illy-nourished and neurasthenic by a low grade of catarrhal conjunctivitis and in a large number of cases there was no error of refraction or insufficiency of accommodation. He speaks particularly of the value of mental treatment in these cases when glasses have failed.

86. Optic Neuritis of Whooping Cough.—In the four cases reported, optic neuritis occurred about the fourteenth day of the convulsive stage in one-half the cases, and in the other two after some weeks or months, the connection not being so manifest. Evidences of cerebral trouble, headache, etc., were present in only two cases. Gamble thinks optic neuritis in these cases is probably intraocular. The conclusions suggested are that optic neuritis complicating whooping cough seems to occur more frequently in girls, all his cases being in girls. It may occur with or without evidence of cerebral complication. The vision may or may not be disturbed. The prognosis as to sight is good when there is no cerebral complication. It seems probable that optic neuritis may result from the direct action of toxins or pertussis on the nerve-head.

89. Extirpation of the Lachrymal Sac.—Knapp enumerates the indications for this operation as chronic purulent dacrocystitis resistant to treatment, repeated attacks of acute dacrocystitis with abscess, whenever the sac is dilated whether the contents can be expressed or not, and lachrymal fistula. Either local or general anesthesia may be employed. He makes an incision just below the internal canthal ligament,

passing down and out along the prominent orbital margin for 1.5 to 2.5 cm. The ligament may or may not be divided. If it should be, care should be taken to join the divided parts at the termination of the operation to prevent the possible sinking in of the caruncle. The incision is carried down through the tissue until the sac is exposed. It is usually recognized by its pale red or bluish-red smooth uniform surface. Hemorrhage in the lower part of the incision may be annoying, but can usually be controlled by retraction and compression. The sac is isolated by blunt dissection from its inner wall, proceeding upward, and the cupola freed. It can be more or less lifted out of the fossa. The outer surface must be separated by cutting with small blunt scissors, the attachment above and outward to the canaliculi being carefully separated. It is cut off as low down in the lachrymal canal as possible, and the canal is thoroughly curetted with a small spoon. Then with reflected light a careful inspection is made for any remaining islet of mucous membrane, granulations, inflamed periosteum, or carious bone, which conditions should all be properly met and radically treated. Special care must be used to see that the top of the lachrymal fossa is perfectly clean. If the bone on the inner wall is diseased and superficial curetting be deemed not sufficient, a free opening should be made right into the nose. This enables the removal of the diseased bone and insures proper drainage. The operation is concluded by the exact approximation of the wound edges with two or three sutures, and the cavity is obliterated by pressure on it kept up in the dressings for the next two or three days. The difficulty varies according to the inflammation and adhesions present. Primary union with obliteration of the cavity can be secured in most cases.

90. **Post-Operative Mental Disturbance.**—Twelve cases are reported by Kipp of mental disturbance following operations on the eyes, occurring in both sexes, but mostly in males; the majority had passed middle age. The recovery was very speedy after the patients could be removed to their own homes. He reviews the literature of the subject, that is the ophthalmologic literature, but finds little by American authors. He thinks the cause of the delirium is largely psychic and due to preoccupation on the part of the patient prior to and after the operation. He calls it homesickness, nostalgia with suicidal and homicidal propensities. He has thus far not used restraint but thinks he may have to in future cases. The quickest way to restore the mental equilibrium is to send the patient home. If this is impossible transfer him to some other quarters and give him the society he is accustomed to as far as possible.

91 *The Operative Treatment of Closed Fractures of the Patella. T. W. Huntington.
92 *A Case of Painless Labor, with Special Consideration of the Cause of this Condition, Arthur N. Curtis.
93 *A Bloodless Case of Placenta Previa. W. G. Moore.
94 Diet in Summer Complaint. William F. Waugh.

91. **Fractures of the Patella.**—Huntington reviews the methods and criticises the subcutaneous suture operation as making no provision for toilet of the synovial cavity or adjustment of the aponeurotic fringes and as not by any means a security against germ infection. His routine method is similar to that described and followed by Stimson and other writers: making a transverse incision about 1 c.c. below the point of fracture, clearing the anterior chamber of clots and serum and sponging with small mounted gauze pads, avoiding irrigation as not only unnecessary, but even dangerous. The aponeurotic fringes are carefully everted and held by snap forceps. Any lacerations in the synovial membrane, which are very common, are carefully repaired by suturing with fine catgut. The fragments are then approximated and firmly held while the aponeuroses are sutured with a No. 2 chromicized gut, care being taken as to adjustment, the needle being carried from without inward toward the periosteum, thence under both edges of the fringe and brought out on the opposite side. It is then reversed and inserted about half an inch from the point of emergence, passing from without inward again under both fringes and out at the same distance from the point of original ingress and tied. This gives a mattress suture, the fringes being supported from below by the two lateral arms of the suture, and prevented from becoming re-engaged between the fractured surfaces. The everted edges of the two margins are thus adjusted so as to unite by a firm cicatrix. Another important end attained, he claims, is the prevention of the outward tilting of the fragments, and the securing of the best possible approximation of fractured surfaces. The external wound is closed by silkworm-gut sutures carried through the everted edges of the aponeurosis and thus obliterating the intervening dead space. Over a voluminous dressing, a plaster-of-paris splint is applied, extending from the upper thigh to the ball of the foot and left in place, unless temperature rises, until time for removal of the skin sutures. At the end of the second week in ordinary cases he would cautiously undertake passive motion. Progress will necessarily be slow until the end of the seventh or eighth week, at which time the normal range of the joint movement will be reestablished. He reports a number of cases, all successful.

92. **Painless Labor.**—Curtis reports a case of painless labor in a primipara with a child weighing eight pounds. The patient was neurotic. He explains the phenomenon on the bases of a peculiar anesthesia of the parts due to this neurotic condition. He alludes to the fact that painless labor may be due to hysteria and considers a condition of hysterical uterovaginal anesthesia, not interfering with normal contractions, as probably the cause in this and other like cases.

93. **Placenta Previa.**—In the case reported by Moore, half of the placenta, with about four inches of the cord, was pushed outside without any hemorrhage, and the patient gave birth to a living child of about seven or eight months' development. The other half of the placenta was found adherent to the os uteri and removed without difficulty or hemorrhage. Moore considers this case unique and explains it on the ground of a central implantation of the placenta, which, being thinner than usual, was sufficiently elastic to allow a small head to be engaged, dilating the os, which acted as a stopper until the placenta ruptured, permitting the body to follow it until delivery was completed.

98 Why Have There Been so Few Results from Original Scientific Research in State Hospitals for the Insane? J. U. Wherry.
99 A Contribution to the Literature of Dislocations of the Shoulder. Lewis Schooler.

96. **Spurious Tapeworm.**—Bierring and Albert noticed a peculiar appearance resembling a parasite which they thought probably might be *Tenia nana*, the smallest known tapeworm, but which Stiles proved to be the tissue from a banana. They give illustrations of the appearances.

97. **The Sound of Muscular Contraction.**—Scott describes the sound of muscular contraction, which he thinks is largely responsible for the general vesicular respiratory sound. He has never seen any allusion to this sound in any article on the subject. He has noticed it especially in tetanus, and its absence may be of value in the diagnosis of muscular degeneration, paralysis, atrophy, etc.

104 A Case of Suppurative Parotitis Complicating Pneumonia. C. J. March.

100. **Enuresis.**—Zahorsky notices the various methods that have been employed for urinary incontinence and favors the

cerebral theory of the disorder. The treatment which he has lately followed with considerable success is given by him as follows: Two doses of a diuretic during the day, one at 9 a. m. and the other at 2 p. m., usually the alkaline citrates with spirit of nitrous ether, but he has also used caffein and diuretin, and sodium benzoate. One dose of atropin at night, substituted sometimes by rhus aromatic or antipyrin. He also uses Prendergast's method of cold douching the back. It is too early to speak of positive results, which he promises in a future communication.

101. Anesthetics.—Witherspoon discusses the use of local anesthesia, for which he prefers eucain in most cases. It is not so toxic as cocain and can be sterilized by boiling. It is interesting to notice how little of the drug can be effective. He mentions a case of strangulated hernia operated on with 1/16 of a grain, and he is especially impressed with its effects in partial thyroidectomy. He has also operated with it in cases of empyema with great advantage and used the method in operations on the nerves of the lower extremities. When there is great irritability at the anus and lower rectum he has been rendered the greatest service by injections into the triangular open space at the lower end of the sacrum posteriorly, and in this way has operated on several fissures and fistulas of the rectum. He has tracheotomized the adult three times for the purpose of giving a general anesthetic afterward. In using an anesthetic on the mucous membrane or open surface he relies on cocain, and has no bad effects from its careful use. When general anesthesia is required he prefers chloroform unless contraindicated.

102. Blood in Diseases of the Digestive Tract.—Taussig sums up as follows:

In esophageal affections there is usually no characteristic blood change. In gastric cancer the leucocyte count as such does not always give reliable information. The absence of a digestive leucocytosis, however, is significant, and would be more so if chronic gastritis with dilatation, and especially gastric atrophy, did not produce a similar picture. The latter affection is often characterized by the interesting changes of pernicious anemia. The other gastric affections produce no distinguishing blood changes. Of the intestinal disorders, it is, especially in appendicitis, that the leucocyte count is of value. Here suppuration is characterized by a marked leucocytosis, though this may be absent if the abscess is thoroughly encapsulated. On the other hand, both a mild and a desperately severe case of appendicitis fail to produce leucocytosis.

The blood examination in diseases of the digestive tract, while never giving such precise information as to supplant clinical observation, is often a valuable aid to diagnosis, and should not be neglected.

105. Fractures of the Femur.—The treatment of ununited fractures of the femur are especially noted by Wills, who reports a case and calls attention to the following points: 1. The futility of any treatment except incision, turning out the ends of the bone, freshening them and suturing with heavy silver wire or clamp. 2. The necessity for absolute immobility of the thigh and leg on body by a plaster spica or bandage from toe to waist. 3. The relaxation of calf muscles by flexion of the knee at an angle of 45 degrees. 4. The importance of equable pressure about the entire limb, especially at the seat of the fracture. In his case too large a fenestra was cut in the plaster bandage for drainage purposes. The result is, he thinks, the slight angularity which was observed.

10 The Estimation of Free Hydrochloric Acid in the Gastric Contents. J. J. R. MacLeod.

7. Tuberculosis.—Bulstrode, in his second lecture, gives and discusses the statistics of tuberculosis in Italy, where the figures are apparently lower than in most other European countries, which fact he thinks might be regarded by some persons as affording a strong argument in favor of the adoption of preventive measures, such as were in vogue many years ago in that country. The statistics of Portugal are also given, showing a like decrease, though since 1886 and 1890 there has been an increase in the rate of pulmonary tuberculosis and a greater decrease in other forms, which looks as though there had been some transferment of tuberculosis from one group to another. The figures are of some interest as compared with those of Prussia, which were given in his former lecture. The New York statistics are noticed and compared with those of London, showing that the decrease in New York figures in recent years has been greater than in London, which may in some measure be accounted for by the fact that the scope for decline is less in London than in New York. The records of the American occupation of Havana are interesting, showing a most wonderful decrease in that city under American control. He considers the work of Americans in Havana the most remarkable victory ever achieved by preventive medicine, and quotes the yellow fever statistics to support this statement. In Norway the statistics seem to show a slight increase; perhaps the only country in Europe where this occurs. In England and Wales there has been a slight increase in the rate of fall after 1881 and 1885, but a very marked decline since the 60's. In Australia the death rate from consumption seems to be lower than that of other parts of the world. But while the tendency of pulmonary and other forms of tuberculosis has been downward, that of pneumonia, cancer and heart disease has been on the increase. The fall in the death rate from tuberculosis in Queensland, which is next to the highest rate, is largely due to the decrease in the number of tuberculous natives from the Pacific Islands. There is rather an increase among the whites, and this is almost entirely due to those born in the colony. It is accounted for by Turner in the gradual maturity of the colonists. It is only of late years that many of them have reached the period of early adult life in which the disease claims most of its victims. In Scotland the statistics show a steady decrease. A curious fact is that in the Isle of Man, a sea-girt, wind-swept island, with equable climate and much sunshine, tuberculosis seems to be more common than on larger British islands. Of late years, however, there has been the same decrease as elsewhere. Ireland is another country which does not show a marked decrease in pulmonary tuberculosis, but rather an increase, though the ratio is nevertheless low. This may be largely due to the outflow of the healthiest of the population by emigration. In the conclusion of his lecture he suggests that we should not attribute too much importance to the discovery of the tuberculosis germ. It has not so fundamentally changed the face of affairs as is sometimes maintained.

15. Filariasis.—Flynn reports his experience with this condition. He seems to hold that filaria has a sort of headquarters in the system and if that can be extirpated the parasites disappear from the blood. He gives a case where excision of a tumor in the left spermatic cord apparently completely extirpated filaria which had persisted in the blood after previous operation on other parts. That filaria can exist in the system without causing any symptoms whatever, he holds, is certain, and there are some interesting facts in regard to the entrance of the organisms. He says, if the mosquito bite is the usual mode of infection why is the disease not more common? One of his patients has been married for six years, and during all that time has been a victim of the disorder. His habits are careless, his house full of mosquitoes and his circumstances far from affluent, yet his wife is free from the infection as well as his cat, horse and dog, which show no signs of the disorder. He has not recognized household infection in any one of his series of cases, and, under the impression that tank water might supply some clue, he centrifuged several gallons of water from tanks containing the filaria mosquitoes, with negative results. As regards treatment, the rational method is to kill the parent organisms in their home or remove them if one can ascertain their abode. In one of his cases alluded to it appeared that he had removed them. It is more difficult, he finds, to meet the embryo in the winter, and he thinks it would be interesting to know what results residence in a cold climate would have on these patients.

20. Surgical Treatment of Dyspepsia.—The operative treatment of dyspepsia in cases of adhesions producing symptoms which can only be relieved by mechanical means is mentioned by Bird, and also adhesions connected with malignant disease. Adhesions also play a prominent part in chronic pancreatitis, which may reveal itself by tumor and be relieved by opening the gall bladder. With chronic pancreatitic adhesions and dyspeptic symptoms later, the resemblance to cancer is close, but even at the time of operation the nature of the condition present may be dubious. The healing of a gastric ulcer may cause dyspeptic symptoms with disability, which may only be relieved by operation. This is one of the most obvious occasions where the surgeon can intervene in long-standing gastric disorder. There are other adhesions in the perigastrium which may give rise to symptoms referable to the stomach, which he has noticed in earlier articles. The further experience of himself and friends only supports the position that he then took. Adhesions of variable causation in the epigastrium engender the symptoms of indigestion. They may produce

epigastric distress on slight provocation or without occasion, rendering the patient a permanent dyspeptic. They may even lead to severe and fatal illness. In one case where he had diagnosed such a condition the patient died from uncontrollable pain and vomiting and postmortem examination disclosed perigastric adhesions as the only apparent cause of death. When medical treatment fails, the surgeon may then intervene. Surgery can cure some cases of intractable dyspepsia easily and with the slightest risk. Others may be much improved and there is always the possibility of discovering malignant disease by operation.

22. **Common Stomach Disorders.**—Stawell notes those cases where there is a so-called functional disorder, nervous dyspepsia, though they may sometimes be associated with slight organic disease as in the dyspepsia of phthisis, which may cause serious derangement of digestion simply due to defective nutrition. Well-regulated rest and large meals insisted on will often relieve such conditions. The examination of the stomach contents should form the basis of diagnosis, but he comments on the neglect of the stomach tube by British medical men. He does not consider excessive tea drinking the cause of dyspeptic symptoms originally, as it is not the intolerable amount of tea, but the diminution of solid food associated with drinking which causes the gastric disturbance. The odorless and tasteless eructations and belching which occurred in one of his cases, comparable to hiccough caused by gastric irritation, are to a considerable extent controllable by voluntary effort. The ordinary eructations are not due to fermentative changes any more than is the "wind" or "hiccough" of infants. If the eructations are markedly acid there usually seems to be a secretory gastric irritability aroused by any particularly stimulating kind of food or drink. This must be classed as a neurosis and should receive the simplest symptomatic treatment by local "antacids." In conclusion he mentions gastric ulcer and chronic gastric catarrh with excessive mucus. The cause of the former is not known, and it may give some difficulty in diagnosis. Where there is doubt there should be some hesitation in the use of the stomach tube. He, however, does not hesitate to treat a suspicious case of gastric ulcer as if this diagnosis was certain. The commonest cause of gastric catarrh is not over-feeding or even improper food, but the abuse of alcohol; complete abstinence is often the very best treatment.

24. **Retrodeviations of the Uterus.**—Hooper criticises the methods of antefixation of the uterus and quotes from authorities, Dudley, Reed and others as to the dangers and impracticability of such methods, especially in child-bearing women. He thinks the most satisfactory results in such cases come from four or five weeks in bed with good nursing and the use of ichthyol tampons with hot vaginal irrigations and massage to reduce the subinvoluted uterus to its normal size, then a carefully adapted pessary and proper treatment for any existing endometritis are far better in uncomplicated cases. They are all, he thinks, that are needed to effect a relief of symptoms. If inflammation of the appendix or adhesions complicate the case, no surgeon would recommend the shortening or fixation operation. He reiterates his conviction that shortening operations such as the Alexander, Kelly and others should never be employed in single women or those who have not reached the menopause, even if we admit their usefulness in uncomplicated cases of retrodeviation in other women.

34. **Pyocyaneus Infection of the Bladder.**—Barth describes a case of cystitis following la grippe in which the *Bacillus pyocyaneus* was found in pure cultures. Faltin has also reported similar findings in 4 out of 86 cases of cystitis. In 15 other cases it was associated with other bacteria. Neither urotropin nor salol proved efficient in conquering the infection. Barth's patient took 2 gm. of urotropin daily without banishing the bacilli, and rinsing the bladder with antiseptics likewise failed to dislodge them. But the symptoms of cystitis disappeared under this treatment and the pyocyaneus, although still present, seemed to have lost all virulence and persisted as an ordinary saprophyte.

37. **Is There a Bothryomycosis?**—Bosc gives histologic notes of 4 cases of lesions supposed to be caused by bothryomyces, but he denies this explanation and affirms that the lesions are merely fibro-papillomata secondarily infected with staphylococci.

40. **Treatment of Stricture of the Urethra.**—Desnos proclaims that fine and durable results can be attained by combined progressive dilation with electrolysis with a weak current. He fastens the negative electrode to an ordinary metal sound, with the positive electrode on the thigh. The current is turned on for ten to fifteen minutes, but not stronger than 3 to 4 milliamperes. This procedure is repeated at intervals of six to eight days. In 20 cases thus treated the dilation seemed to be more durable and the most rebellious strictures yielded after a few applications, while the walls seemed to become more flexible than by other methods of treatment.

42. **The Debuts of the History of Appendicitis in France.**—This address by Kelly was delivered before the French Société de Chirurgie in June, and created something of a sensation. Baudouin's witty comment was quoted recently in The Journal in the foreign news column.

47. **Curable Forms of Meningeal Hemorrhage.**—Widal has established the value of lumbar puncture for the diagnosis of meningeal hemorrhage, and Chauffard now enumerates the cytologic and chromatic findings which establish the prognosis. He describes 2 cases in detail which terminated in recovery. Kernig's sign was not found in either, but the aspect of the cerebrospinal fluid was alike in both. At first it contained a large proportion of blood, but in the three or four successive punctures the fluid was seen to lose its blood and

lymphocytosis became pronounced as the fluid grew a limpid yellow. There was no polynuclear phase. The fluid was drawn into 3 tubes each time for better comparison, and the last trace of a clot did not vanish till after the eighteenth day.

48. **The Chlorids in Nephritis.**—Widal has coined the term "dechloridation" to express the treatment of epithelial nephritis by reducing the amount of salt. He found that daily ingestion of 10 gm. of salt by 4 patients affected with arteriosclerosis and interstitial nephritis, caused no disturbances, no edema, nor any discomfort. On the other hand, pronounced edema was produced in 2 out of 3 patients with epithelial nephritis. In a similar case in which the chlorids were determined for 62 days he was able to induce the edema to appear and disappear at will by administration of salt. The degree of the albuminuria followed the fluctuations in the chlorid curves. This patient was a man of 62, and the details of the metabolism while these tests were being made are given in tabulated form. Edema and albuminuria had previously invariably followed ingestion of solid food, and invariably subsided on a milk diet. By adding salt to the milk the edema could be reproduced at will, and by giving solid food without salt the edema could be promptly banished. These abrupt changes were made nine times and always with the anticipated effect. The albumin in the diet is immaterial; it is the salt alone that is responsible for the edema. The latter subsided even on a hearty meat diet if salt were withheld. Salt should not be fed to cows that supply milk for nephritis patients, and the normal proportion of salt in milk might be thus avoided. Temporary dechloridation can thus be accepted as an important factor in the treatment of epithelial nephritis and allows a much wider range of diet.

57. **Medicine at the Prado.**—Meige gives 12 photographs of masterpieces of painting that hang in the famous museum at Madrid, which portray subjects specially interesting from a medical point of view. In some the famous court dwarfs are depicted, in others the alleged extraction of stones from the head, the village barber, tooth-puller, court jester, etc. His list closes with a portrait of Charles V, marked by the adenoid expression and pronounced prognathism noted in all the portraits of his race in the various museums of Europe.

58. **Operations on a Single Kidney.**—In the case of cysts in a solitary kidney reported by Winter, the patient died after extirpation. He finds 11 similar instances in the literature in which an operation was undertaken on a solitary kidney. In the 7 cases in which nephrectomy was done none of the patients survived, but the 4 treated by nephrotomy all recovered. The lesions were due to stones, an abscess or pyonephrosis in the latter cases.

60. **Appliance for Raising Part of the Body.**—König gives illustrations of the convenient little cross-board which fits into cross grooves in the operating table and can be raised to the desired height by turning a crank.

61. **Lymph Nodes in Salivary Glands.**—Brunn found in 2 out of 23 cases examined genuine lymph nodes embedded in the submaxillary salivary glands.

69. **The Murphy Button.**—Neuweiler analyzes the results as published in 185 reports of operations on the stomach and intestines in which either the Murphy button or the Czerny-Lembert suture was used. He also reviews his own experience in 33 operations from the same point of view. His conclusions are that the suture is in certain circumstances to be preferred to the use of the button, especially in operations on the large intestine, and in lateral anastomosis of the large with the small intestine. Lateral anastomosis of the small intestine is best done with suture, except in case of gangrene requiring resection. The button should not be used in an anterior gastroenterostomy on account of cancer, nor in a posterior for benign stenosis of the pylorus.

70. **Circular Suture of Vessels.**—Jensen's numerous experiments were made principally on horses. He employed the various methods of suturing and bone, ivory or absorbable magnesium prothesis. The results indicate that thrombosis in such circumstances is due to infection, and consequently intervention of this nature should be undertaken only in an aseptic region. A prothesis is no advantage and has the drawback that it narrows the lumen. In his experience the best suture was the U-shaped union which brings a broad surface of the intima on both stumps into contact without narrowing the vessel. He found silk the best suture material for the purpose.

74. **Luxatio Sterno-clavicularis from Tending a Machine.**—Katzenstein's patient and the four other cases on record were lads of 17 or thereabouts whose work compelled them to incessantly reach with both arms and then pull backwards with great strength. The elastic fibers of the capsules of joints are not fully developed at this age and they become overstretched and exhausted with a chronically recurring trauma of this kind.

77. **Isolated Fracture of the Scaphoid.**—Lilienfeld encountered 7 cases of isolated, subcutaneous fracture of the scaphoid in the wrist in a recent series of 128 fractures. In all the fracture occurred from trauma acting on the hand in dorsal flexion and radial abduction. It may be diagnosed from the anamnesis.

78. **Anti-Plague Immunization.**—Kalle and Otto report from the Berlin Institute for Infectious Diseases that their experi-

ments and tests fail to show any particular benefit from the Haffkine method of immunizing against the plague. They consider the injection of avirulent living cultures of plague bacilli a true and effective means of vaccination. A single injection conferred on laboratory animals complete immunity for months with no phenomena of infection and merely a slight increase of the plague germs at the vaccinated spot. More than 80 per cent. of the rats and 60 per cent. of the guinea-pigs are still completely immune three months since the vaccination. The immunity conferred by the Haffkine method lasts at most only six weeks. The cultures were rendered avirulent by long cultivation at 40 to 41 C.—a particularly non-virulent culture being selected for the purpose. Three loops of this culture could be injected into guinea-pigs without symptoms, that is, more than three thousand times the lethal dose of a virulent culture.

79. **Amaurotic Family Idiocy.**—Sach's article appeared in the *Journal of Nervous and Mental Disease*, January, 1903.

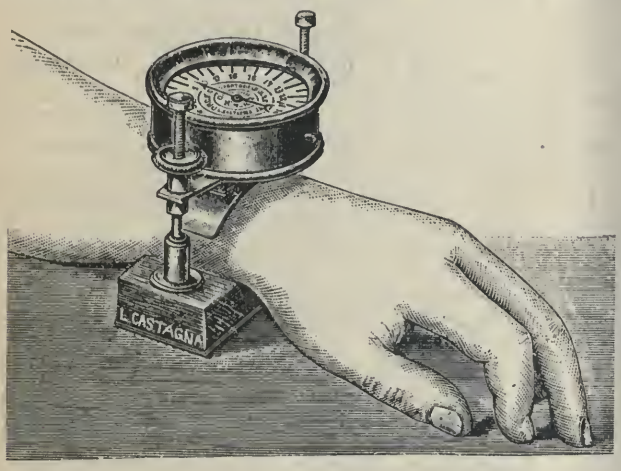
80. **Diagnosis of Malignant Thoracic Tumors.**—Feldt reviews 3 published cases and reports 2 personally observed in which a malignant intrathoracic tumor was diagnosed from particles of tissue in the sputa. He gives cuts of the findings in his cases and affirms that such tumors could be diagnosed more frequently than is the case at present if in suspicious cases hemorrhagic sputa were examined against a black background for small scraps of tissue and the latter investigated by the usual histologic technic.

82. **Influence of Heat on Coagulation of Milk.**—Silberschmidt's research establishes that cow's milk heated too long or too hot entirely loses its property of coagulating under the action of rennet.

83. **Modified Alcohol Compress Treatment.**—Beschoren regards Salzwedel's alcohol compresses as an indispensable aid in the treatment of local inflammatory processes. Even if the phlegmon, panaris or lymphangitis does not retrogress, as usually occurs, the formation of a superficial abscess is hastened and after-treatment facilitated. Salzwedel applies gauze moistened with alcohol to the spot, covered with dry gauze and fastened with a perforated impermeable outer covering. Beschoren has found that the part sometimes smarts with this application, and modifies it by adding to the alcohol an equal amount of a 1 per cent. solution of aluminum acetate. The chemical combination raises the temperature of the fluid several degrees and the application is always soothing. He applies the rubber tissue directly over the moistened gauze and the cotton outside, and recommends this technic as an ideal method of treatment for local inflammatory processes. He reports a few cases in detail.

85. **Etiology and Treatment of Sclerosis of Middle Ear.**—Stenger ascribes many cases of sclerosis of the middle ear to disturbances caused primarily by swelling of the turbinate bones or some other anomaly in the nose affecting the eustachian tubes. Prompt attention to subjective ear symptoms and removal of the primary factor in the nose may arrest the incipient ear affection and relieve it in many advanced cases. He relates two typical instances in which the patients were restored to their business by the relief of the deafness after partial resection of some of the turbinate bones, supplemented by electric massage and catheterization.

87. **Anuria.**—Apolant reports a case of complete anuria for nine, and later for eight days, terminating in recovery. He assumed that a stone had become impacted in one ureter and the other had contracted by a reflex spasm, and administered belladonna on this supposition. The symptoms became alarming the eighth day, and Nitze passed a catheter into the right ureter, allowing evacuation of ten quarts of urine in the first twenty-four hours. The patient was an elderly, gouty subject and the projected nephrotomy might have had serious consequences.



88. **Mechanical Treatment of the Prostate.**—Laskowski gives cuts of two instruments he has devised to apply vibration massage to the prostate through the rectum or the abdominal wall. He also describes another which allows the application of cold at the same time.

122 Women in Medicine. L. Stieda.—Ueber die Zulassung der Frauen zum med. Studium.

90. **Pulse Controller for Narcosis.**—Gaertner's experience with chloroforming animals has convinced him that the usual cause of death in narcosis is the depression of the blood pressure. Dogs succumb to chloroform much more readily than man, but he found that invariably the animals could be saved if close watch were kept on the blood pressure and as soon as the pulse became fainter proper measures were adopted. He has also learned that it is impossible to rely with accuracy on even the most skilled digital examination of the pulse, as perception becomes deadened under certain circumstances. For these and other reasons which he details, he regards the little apparatus he has devised as an invaluable contribution to the technic of chloroform anesthesia. It is somewhat on the principle of his ring "tonometer," which is coming into current use. He remarks that Mikulicz has reported three deaths under chloroform of subjects in convulsions. During convulsions the blood pressure is extremely high, and exceptional caution is necessary in this condition, as the narcosis is liable to raise the already extremely high blood pressure to a dangerous height. In one of Gaertner's patients, a man of 76, the average normal pressure was 155, and it rose during the narcosis to 220; and in a woman of the same age it rose from 176 to 215, although the anesthesia was superficial. Such a rise might be fatal in certain conditions.

The blood pressure should always be determined as a routine measure before giving chloroform and a venesection may be indicated. He adds that his pulse controller has been used by a number of operators and in more than 200 operations, and all express delight at the reliability of the instrument and the relief from anxiety it affords, enabling the narcosis to

be safely steered to its conclusion. The language spoken by the apparatus is only imperfectly understood as yet, but time will undoubtedly render some such device as indispensable as the thermometer.

91. **Treatment of Face Presentations.**—Anselm compares the reports of various maternities and shows that expectant treatment has produced fully as good if not better results in the hands of Fehling, Bumm and v. Herff as Opitz's intervention.

92. **The Toe Reflex.**—Richter cites statistics to show that Babinsky's sign was positive in 1.8 per cent. of 500 healthy persons tested. Notwithstanding this occurrence of the sign in a few healthy persons, he regards the reflex as a very valuable presumptive evidence of some disturbance in the function of the pyramidal tracts.

93. **Improved Mask for Ether.**—Longard reports 2,700 ether narcoses in which his mask was used, and in only 2 was there a trace of the stage of agitation. He thinks the latter is due more to carbonic acid gas intoxication than to the ether, and this is avoided with his mask. His experience has shown that there are no contraindications to the use of ether by this method. Only 15 to 30 c.c. of ether are required for women and children, and 40 to 60 c.c. for men. An hour's narcosis requires 75 gm. for women and men and 100 gm. for hard drinkers.

94. **Malignant Scarlet Fever.**—Günther reports an epidemic of 150 cases of this disease, affecting adults mostly, and fatal in less than twenty-four hours in a large majority of the cases. All those in which the brain was affected from the start terminated in death.

96. **Tar to Reduce Dust in Roads.**—The experiments at Monaco and elsewhere with crude petroleum have not proved very successful as the results were not durable. But the application of boiling coal tar produces a coating like cheap asphalt, which has lasted eight months to date and fully answers the desired purpose. The total expense is only $80 for a kilometer of a road 15 feet wide, that is, about $128 a mile, with coal tar $6 to $10 a ton.

97. **Galvanocautery Punctures in Tuberculosis of the Throat.**—Grünwald explains that there is little hope of a cure unless the deep-lying infiltrations are drained. This is accomplished by puncture with the pointed galvánocautery. The immediate relief afforded is surprising, while there is slight if any reaction. He gives cuts of several cases. From two to five punctures are required.

105. **Antistreptococcus Serum.**—The long series of researches described have demonstrated that antistreptococcus serum acts by stimulating phagocytosis and absorption. The best results are attained with large doses in the early stage of acute streptococcus infection. Serum made from freshly cultivated human streptococci is the only one that is effective, but its results on animals can not be applied to man.

107. **Anastomotic Circulation of the Heart.**—Galli reports a case at Baccelli's clinic in which the mouth of the right coronary opening into the aorta had been entirely obliterated by a sclerous neoformation. The closest scrutiny failed to reveal any sclerous alterations in the right heart and only a single sclerous focus in the rear of the left heart. The patient was a syphilitic and had had articular rheumatism twice. Galli gives cuts of the heart showing an anastomosis between the right and left coronaries which explained the lack of nutritional disturbances.

108. **Massage of Recent Fractures.**—Jordan is an advocate of early massage, and states that out of 73 patients, of whom 27 were over 40 years old, 67 recovered complete working capacity after fracture of arm or shoulder, and only 2 are much incapacitated. His principles are: for the upper extremity, massage and mobilization, supplemented by fixation after each massage in case of fracture of a joint or of the shaft without material dislocation. For the leg, massage should be restricted to the joints, in combination with a walking apparatus. In fractures of the long bones of the leg, massage is only a preliminary.

114. **Morphin-Scopolamin Narcosis in Gynecology.**—Flatau tabulates the details of 47 cases in which this method of narcosis was employed, and concludes with the warning that it is unsuitable and dangerous for the majority of physicians, for surgical intervention and especially for obstetric operations.

115. **New Material for Protection Against X-Ray Burning.**—The sheet lead used to protect the sound skin in *x*-ray exposures leaves smutty marks on skin and clothing, looks unsightly and dirty even when new, and soon cracks. Holzknecht has remedied all these defects by having a coating of vulcanized rubber applied on each side of the sheet lead. This rubber-coated lead lasts indefinitely without cracking. He finds the most convenient shape to be a long rectangle with a semicircle cut out at one end. By having a number of these sheets with semicircular openings of different sizes they can be arranged around the part to be exposed leaving an opening of the desired diameter.

117. **Epidural Injections.**—Strauss tried this method in the mercurial treatment of 10 syphilitics, but soon abandoned it as possessing no advantages over the usual methods. But in enuresis, impotence, sexual neurasthenia and allied conditions the results were remarkable improvement or complete cure. In 7 cases of incontinence only one or two injections were required. In 2 cases of nocturnal emissions one was cured and the other much improved by the same, as also 2 cases of impotency. A patient with general sexual neurasthenia was essentially improved, but a second one of this class failed to derive any benefit. He injects 5 to 30 c.c. of a solution of cocain, .01 gm.; sodium chlorid, .2 gm., and distilled water to 100 gm., adding two drops of 5 per cent. aq. carbol. He uses a platinum-iridium needle 6 cm. long and 1 mm. thick with the syringe illustrated in THE JOURNAL of July 25, p. 287. He makes the injection slowly by puncturing the sacral canal, and as it is very tolerant the injection can be soon repeated; one to five days is his average interval.

121 **Yohimbin as a Local Anesthetic.**—Magnani corroborates the testimony of others in regard to the value of yohimbin for local anesthesia. In his ophthalmologic practice he found that it affected the tissues like tropacocain while it resembled cocain in its anesthetic effect.

Hygiea, Stockholm.

123 (No. 4.) Physiologic Action of Alcohol. C. G. Santesson.—Om alkoholens fysiolgiska verkningar.
124 *Leucocytosis in Appendicitis. G. Nilson.—Kasuistikt bidrag till fragan om leukocytosens betydelse vid appendicit.

138 Six Cases of Extra-uterine Pregnancy.—Extrauterint hafvandeskap.
139 Campaign Against Tuberculosis. R. v. Post.—Kampen mot tuberkulosen ute och hemma.

124. **The Leucocytes in Appendicitis.**—Nilson reports the details of 17 cases showing the value of the blood count as an aid in diagnosing. In 9 cases there proved to be no suppuration and the leucocytes ranged from 7,500 to 18,000 during the first two days and then rapidly subsided to normal. In only one instance was the number 20,000 to 26,000 for five days. The appendix was obliterated by catarrhal inflammation, but there was no abscess. In the other cases the leucocytes numbered 18,000 to 29,700, and the appendix was found perforated and inclined to gangrene. An abscess in the groin was operated on in one patient, with a leucocytosis of 14,500 to 23,000. The whites still remained above 12,800 and a subphrenic abscess was discovered and evacuated six days later. The whites still continued to rise and reached 21,200, when the appendix was extirpated a week later. The leucocytosis continued and rose to 26,000, but after evacuation of a small gaseous abscess found in the Douglas pouch, the whites dropped to 10,000 in two days after having been continuously in the neighborhood of 20,000 for nearly a month. In 2 cases of diffuse purulent peritonitis the leucocytes reached 27,200 and 40,000.

127. **Cancer Research.**—Sandberg's article is a study of the 2,153 cases of cancer treated at the Sabbatsberg Hospital, 1879-1901. Less than one-third were on male subjects and in half of these the cancer was located in the stomach (315 out of 623 male patients). About 1.71 per cent. of all the male patients received during this period were affected with cancer, and 4.32 per cent. of the women patients, the total number of patients being 71,839. He gives the particulars, remote results after operations, etc. Cancer in the stomach developed without metastases in 52.5 per cent. of the 229 cases in women, and in 54.7 per cent. of the 315 male cases. Metastases were most frequent with cancer in the liver, and they were found in 101 out of 483 cases of cancer of the uterus, and in 131 out of 288 on the mamma.

129. **May's Symblepharon Operation.**—Landström applied in 4 cases the operation suggested by May in 1899. He regards it as the best method to date, although not ideal. The results were extremely satisfactory in his cases, as he shows by photographs.

132. **First Aid in Germany and Austria.**—Boman describes the volunteer "Samaritan" associations in the German-speaking countries and the training of their members in the first aid to wounded persons and in emergencies of various kinds. He urges similar organizations elsewhere.

133. **Acute Psychoses in Syphilis.**—Marcus' article is an exhaustive study of this subject and its literature. He has personally observed 11 cases and analyzes them and 6 others reported by Brewer and Bailey, Jolly, Fournier or others. All recovered under specific treatment except 2. He gives cuts of the autopsy findings in one case, showing the typical circumscribed basal meningitis, etc. His patients were from 26 to 53 years old. There was no hereditary taint or abuse of alcohol in the majority.

136 and 137. **Mercuriol Oil.**—This new preparation of mercury in the form of an aluminum magnesium amalgam, contains 90 per cent. mercury. It is similar to mercuriol, but is an oil and specially adapted for injecting purposes. Möller has used it in thousands of cases and has found it extremely effective with the minimum of symptoms of local irritation.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE LATIN GRAMMAR OF PHARMACY AND MEDICINE. By D. H. Robinson, Ph.D., Late Dean of the School of Arts, and Professor of Latin Language and Literature, University of Kansas. With an Introduction by L. E. Sayre, Ph.M., Professor of Pharmacy in, and Dean of Department of Pharmacy, University of Kansas. Fourth Edition, with Elaborate Vocabularies. Thoroughly Revised by Hannah Oliver, A.M., Assistant Professor of Latin, School of Pharmacy, University of Kansas. Cloth. Pp. 277. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A THESAURUS OF MEDICAL WORDS AND PHRASES. By Wilfred M. Barton, M.D., Assistant to Professor of Materia Medica and Therapeutics, and Lecturer on Pharmacy, Georgetown University, Washington, D. C.; and Walter A. Wells, M.D., Demonstrator of Laryngology and Rhinology, Georgetown University, Washington, D. C. Flexible Leather. Pp. 534. Price, $2.50 net; with Thumb Index, $3.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

DISEASES OF THE EAR. A Text-book for Practitioners and Students of Medicine. By Edward Bradford Dench, Ph.B., M.D., Professor of Diseases of the Ear in the University and Bellevue Hospital Medical College. With 15 Plates and 158 Illustrations in the Text. Third Edition, Revised and Enlarged. Cloth. Pp. 718. Price, $5.00. New York and London: D. Appleton & Co. 1903.

THE PRINCIPLES OF OBSTETRICS. A Practical Manual for the Student and General Practitioner. By Stanley Perkins Warren, M.D., Portland, Me., Obstetric Surgeon to the Maine General Hospital. Superbly Illustrated by 165 Line and Half-tone Engravings. Cloth. Pp. 385. Price, $3.00 net. New York: William Wood & Co.

KING'S MANUAL OF OBSTETRICS. By A. F. A. King, M.D., Professor of Obstetrics and Diseases of Women in the Medical Department of the Columbian University, Washington, D. C. Ninth Edition, Revised and Enlarged. Cloth. Pp. 628. Price, $2.50 net. Philadelphia and New York: Lea Brothers & Co. 1903.

THE EXACT SCIENCE OF HEALTH BASED UPON LIFE'S GREAT LAW. By Robert Walter, M.D. Vol. I.—Principles. Leather. Pp. 302. Price, $2.00. New York: Edgar S. Werner Publishing Company. London: Kegan Paul, Trench, Trubner & Co., Ltd.

A NURSE'S HANDBOOK OF OBSTETRICS. For Use in Training Schools. By Joseph Brown Cooke, M.D., Fellow of the New York Obstetrical Society. Cloth. Pp. 391. Price, $2.00. Philadelphia and London: J. B. Lippincott Company. 1903.

PLAIN HINTS FOR BUSY MOTHERS. By Marianna Wheeler, Superintendent of the Babies' Hospital, New York. Illustrated by F. M. Miller. Flexible Leatherette. Pp. 54. Price, 35c. New York: E. B. Treat & Co. 1903.

THIRTEENTH ANNUAL REPORT OF THE EYE, EAR, NOSE AND THROAT HOSPITAL OF NEW ORLEANS, LA. Jan. 1, 1902, to Dec. 31, 1902.

Paper. Pp. 64. New Orleans: A. W. Hyatt Stationery Mfg. Co., Ltd. 1903.

FIRST BIENNIAL REPORT OF THE MONTANA STATE BOARD OF HEALTH. From Its Creation, March 15, 1901, to Nov. 30, 1902. Paper. Pp. 114. Helena: Independent Publishing Company.

THE WELCOME PHYSIOLOGICAL RESEARCH LABORATORIES. Founded 1894. Walter Dowson, M.A., M.D., Director. Cloth. Pp. 36.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the two weeks ending Aug. 8, 1903:

Adair, George W., lieut.-colonel and district surgeon-general, is relieved from duty in the Division of the Philippines, to take effect August 31, and will proceed to the United States and report by telegraph to the Adjutant-General of the Army for further orders.

Bosley, John R., first lieut. and asst.-surgeon, now at Fort McPherson, will report at that post for duty.

Brown, Orville G., first lieut. and asst.-surgeon, now at Washington, D. C., will proceed to Fort Monroe for duty.

Brown, W. E., contract surgeon, is granted leave of absence for two months from about September 1.

Chamberlain, Weston P., first lieut. and asst.-surgeon, is granted leave for one month.

Cable, G. L., contract surgeon, is granted an extension of leave for ten days.

Foster, Charles L., first lieut. and asst.-surgeon, now at Fort Myer, will report at that post for duty.

Fanning, George J., contract surgeon, on his relief from duty at Whipple Barracks by First Lieut. Henry D. Thomason, asst.-surgeon, will proceed to his home at Cacatow, Ariz., for annulment of contract.

Geddings, Edward F., first lieut. and asst.-surgeon, is relieved from duty at Fort Brady, to take effect on the return of First Lieut. William Roberts, asst.-surgeon, to duty at that post, and will then proceed to Fort Keogh, to relieve First Lieut. Paul C. Hutton, asst.-surgeon.

Gregory, Junius C., first lieut. and asst.-surgeon, is granted leave for one month, to take effect when he is relieved from duty at the U. S. General Hospital, Washington Barracks.

Hutton, Paul C., first lieut. and asst.-surgeon, will proceed to Pekin, China, and report to the commanding officer of the U. S. legation guard for duty, to relieve First Lieut. Frederick M. Hartsock.

Hartsock, Frederick M., first lieut. and asst.-surgeon, will proceed to the United States and report by telegraph to the Adjutant-General of the Army for further orders.

Hallock, Harry M., captain and asst.-surgeon, now at the U. S. General Hospital, Presidio, is relieved from further duty in the Division of the Philippines, and will proceed to Fort Porter for duty.

Hutton, Paul C., first lieut. and asst.-surgeon, is granted leave of absence for one month.

Jones, Percy L., first lieut. and asst.-surgeon, now at Atlanta, Ga., will proceed to Fort Monroe for duty.

Jones, John F., contract surgeon, is granted leave of absence for one month, with permission to apply for an extension of one month, to take effect on his relief from duty at Fort Washakie.

Kieffer, Charles F., captain and asst.-surgeon, will report to Major William H. Arthur, surgeon, president of the examining board at the Army Medical Museum Building, Washington, D. C., for professional examination and physical re-examination for promotion.

Lovering, Robert C., first lieut. and asst.-surgeon, now at Philadelphia, Pa., will proceed to Fort Leavenworth for duty.

Morris, Samuel J., first lieut. and asst.-surgeon, now at Fort Grant, will proceed to San Francisco and report for transportation to the Philippine Islands, where he will report for assignment to duty.

Mabee, James I., first lieut. and asst.-surgeon, now on temporary duty at Presidio, is assigned to permanent duty at that post.

Purnell, Harry S., first lieut. and asst.-surgeon, now at Fort Wingate, will proceed to San Francisco, Cal., and report for transportation to the Philippine Islands, where he will report for assignment to duty.

Pinkston, O. W., contract surgeon, is granted leave for one month, to take effect on the termination of the season of target practice at Camp Stoney Point, N. Y.

Peed, George P., first lieut. and asst.-surgeon, now at Portsmouth, Va., will proceed to Washington Barracks, and report at the U. S. General Hospital for duty.

Porter, Ralph S., first lieut. and asst.-surgeon, now at Chicago, will proceed to Fort Leavenworth for duty.

Palmer, Fred W., first lieut. and asst.-surgeon, now at Brooklyn, Mich., will proceed to Jefferson Barracks for duty.

Pipes, Henry F., first lieut. and asst.-surgeon, now at Fort Barrancas, will report at that post for duty.

Siler, Joseph F., first lieut. and asst.-surgeon, now at Fort McPherson, will report at that post for duty.

Stedman, Chester J., first lieut. and asst.-surgeon, now at Fort Adams, will report at that post for duty.

Smith, Charles F., contract surgeon, is relieved from duty at Fort Leavenworth, and will proceed to his home, Whitehall, Mich., for annulment of contract.

Smith, Charles F., contract surgeon, is granted leave of absence for one month.

Sabin, Wallace E., contract surgeon, is relieved from duty at Fort Apache and will proceed to Vancouver Barracks for duty.

Richards, J. W., contract surgeon, is granted leave of absence for one month on surgeon's certificate.

Ten Eyck, Benjamin L., major and surgeon, having been found by an Army retiring board incapacitated for active service on account of disability incident thereto, his retirement from active service, Aug. 3, 1903, under the provisions of Section 1251, Revised Statutes, is announced. Major Ten Eyck will proceed to his home.

Trenholtz, C. A., contract surgeon, is granted an extension of leave for fourteen days.

Van Kirk, Harry H., contract surgeon, is relieved from further duty at Fort Wingate, and will proceed to Fort Washakie and report for duty, to relieve Contract Surgeon John F. Jones, who will proceed to Fort Schuyler.

Whaley, Arthur M., first lieut. and asst.-surgeon, now at Sault Ste. Marie, Mich., will proceed to Fort Sheridan for duty.

Winter, Francis, captain and asst.-surgeon, is relieved from duty as attending surgeon and examiner of recruits at St. Louis, Mo., to take effect on the expiration of his present leave, and will then proceed to Fort Huachuca for duty.

Wood, Halsey L., contract surgeon, is relieved from duty in the Department of the Columbia, and will proceed to his home, New York City, for annulment of contract.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended Aug. 8, 1903:

Surgeon L. W. Spratling, Asst.-Surgeons C. H. DeLancy and E. M. Blackwell and Pharmacist C. E. Reynolds, detached from the *Columbia* and ordered to the *Hancock*.

Asst.-Surgeon H. L. Brown, detached from the Naval Proving Ground, Indian Head, Md., and ordered to the Navy Yard, Washington, D. C.

Asst.-Surgeons K. Ohnesorg and J. T. Kennedy, ordered to the Naval Academy.

A. A. Surgeon C. T. Grayson, ordered to the Naval Proving Ground, Indian Head, Md.

Pharmacist J. Cowan, detached from the Navy Yard, Boston, Mass., and ordered to the Naval Magazine, Iona Island, N. Y.

Pharmacist E. T. Morse, detached from the Naval Magazine, Iona Island, N. Y., and ordered to the Navy Yard, Boston.

Pharmacist E. May, ordered to the Naval Hospital, Norfolk, Va.

P. A. Surgeon J. A. Guthrie, detached from the *Vicksburg* and ordered to the *Solace*.

Asst.-Surgeon R. H. Michels, detached from the *Solace* and ordered to the *Wilmington*.

Asst.-Surgeon G. M. Mayers, detached from the *Isla de Cuba* and ordered to the *Vicksburg*.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended August 8, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, July 25-August 1, 3 cases.
California: Los Angeles, July 18-25, 5 cases.
Illinois: Chicago, July 25-August 1, 4 cases; Danville, July 25-August 1, 1 case.
Louisiana: New Orleans, July 25-August 1, 3 cases.
Maryland: Cumberland, July 1-31, 7 cases, 1 death.
Massachusetts: Fall River, July 25-August 1, 7 cases, 1 death.
Michigan: Grand Rapids, July 31-August 1, 1 case.
Missouri: St. Louis, July 25-August 1, 2 cases.
New Hampshire: Manchester, July 31-August 1, 2 cases.
New Jersey: Camden, July 31-August 1, 1 case.
Ohio: Cincinnati, July 24-31, 1 case; Toledo, July 25-August 1, 1 case.
Pennsylvania: Scranton, July 25-August 1, 3 cases.
Utah: Salt Lake City, July 31-August 1, 2 cases.
Wisconsin: Milwaukee, July 13-August 1, 14 cases.

SMALLPOX—FOREIGN.

Austria: Prague, July 11-18, 2 cases.
Belgium: Brussels, July 11-18, 4 deaths.
Brazil: Rio de Janeiro, June 29-July 12, 14 deaths.
Colombia: Bocas del Toro, July 14-21, 1 case, 1 death.
Ecuador: Guayaquil, July 4-11, 1 death, sporadic.
Germany: Bremen, August 1, 1 case on Steamship Bremen.
Great Britain: Dublin, July 11-18, 6 cases, 1 death; Manchester, July 11-18, 2 cases, 1 death; Newcastle-on-Tyne, July 11-18, 4 cases.
India: Bombay, June 23-July 7, 28 deaths; Calcutta, June 27-July 4, 1 death.
Mexico: Tampico, July 18-25, 1 death.
Russia: Moscow, July 4-11, 4 cases, 3 deaths; Riga, May 1-31, 24 deaths; St. Petersburg, July 4-18, 37 cases, 3 deaths.
Spain: Barcelona, June 20-July 4, 4 deaths.

YELLOW FEVER.

Colombia: Panama, July 13-27, 7 cases, 2 deaths.
Costa Rica: Limon, July 16-23, 9 cases, 4 deaths.
Mexico: Coatzocoalcos, July 18-25, 2 cases; San Luis Potosi, July 13, present; Tampico, July 18-25, 40 deaths; Vera Cruz, July 18-25, 34 cases, 17 deaths; Yucatan, July 15, present.

CHOLERA.

India: Bombay, June 30-July 7, 1 death; Calcutta, June 27-July 4, 27 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, July 19, 1 death.

PLAGUE—FOREIGN.

Africa: Cape Colony, June 6-13, 5 cases, 4 deaths.
China: Amoy, June 20, 50 deaths daily, estimated.
Egypt: Alexandria, June 27-July 4, 4 cases, 1 death; Port Said, June 27-July 4, 1 case; Tantah, June 27-July 4, 2 cases, 2 deaths.
French Indo-China: Tonquin, June 10-23, 5 deaths.
India: Bombay, June 23-July 7, 178 deaths; Calcutta, June 27-July 4, 15 deaths; Karachi, June 14-21, 9 cases, 8 deaths.
Japan: Yokohama, June 20-27, 2 deaths.

PNEUMONIA AND PLEURISY IN EARLY LIFE SIMULATING APPENDICITIS.*

J. P. CROZER GRIFFITH, M.D.

Clinical Professor of the Diseases of Children in the University of Pennsylvania.

PHILADELPHIA.

Attention has been recently called in several quarters to the simulation of appendicitis or peritonitis by pulmonary processes, especially pneumonia and pleurisy. The fact that this simulation often occurred has long been known, but is commonly overlooked, and, inasmuch as the diagnosis is certainly at times extremely difficult, and since operation for appendicitis has even been performed when only pneumonia was present, I have thought it of interest to report a few cases of this nature and to quote those of like sort which have come to my notice in medical literature, limiting myself entirely, at least in detailing cases, to the occurrence of the condition in early life. It is, indeed, at this time that the confusion is most likely to happen, although some cases developing later in life are also met in literature.

Of the cases reported here the first two have already been detailed by me in previous publications; the others have not. Two of them occurred in the private practice of Dr. H. R. Wharton, and the notes of them were kindly given me by him.

CASE 1.—Mary Agnes McC., aged 8 years, admitted to St. Agnes' Hospital Oct. 27, 1893, suffering from chorea. On November 15 she became suddenly ill with very severe abdominal pain and tenderness and with such a marked appearance of some grave condition that the resident physician feared arsenical poisoning. The temperature was elevated, the pulse 170, and the respiration from 80 to 90 and very shallow. There was severe abdominal pain, with tenderness. The details of the condition as reported to me made me suspect peritonitis.

I examined her on November 16 and found that the abdomen was very much distended and tender; there was abdominal pain; the expression of the face was anxious, and the legs were held constantly drawn up in bed. The temperature had risen to 102. The rapidity of respiration combined with its shallowness appeared to be dependent on peritonitis, and several physicians who saw her with me agreed that this was the undoubted diagnosis. There was no cough. A physical examination of the lungs was made, however, as a routine, and to our surprise the upper part of the right lung was found to exhibit pneumonic consolidation. By the evening of the next day all abdominal symptoms had disappeared.

CASE 2.—Simon L., 4 years old, admitted to the Children's Hospital January 19, 1899. He was taken acutely ill on the 14th with obstinate constipation, abdominal pain and distension, and tenderness in the right iliac fossa. Cough was not noted, if present. The physician who saw him had already made the diagnosis of appendicitis, but the child was admitted to the medical wards, inasmuch as operation had been forbidden by the parents.

On examination on the 20th the child was found evidently in much pain; had an anxious expression of face, shallow respiration of from about 30 to over 40 per minute, and held the legs drawn up most of the time. The abdomen was not distended, but was tender in the right iliac region and everywhere rigid enough to make palpation difficult. As far as it was possible to determine no tumor was present. The temperature varied from 103 to 105. Except for a few coarse râles, nothing could be detected on examining the lungs in front. Owing to the great distress of the child, and because the diagnosis of appendicitis seemed so positive, the posterior part of the chest was not examined on this date. On the next day, the 21st, pneumonic consolidation of the left lung was easily found. The abdominal symptoms remained unchanged. On the 22d all abdominal symptoms had disappeared. Crisis occurred on the 24th.

In neither of these cases was there apparently any reason to suspect anything but an appendicitis, or a peritonitis secondary to this. In the light of later experience, however, one sees that certain suspicious symptoms were present. The height of the fever in the second case, and, especially the rapidity of the respiration, ought to have rendered me more cautious in diagnosis. It is certain that in the second case the child would have been at once transferred to the surgical ward for operation if this had been permitted by the relations, and that operation might have been done if a more careful examination had not been made.

CASE 3.—Myer M., 6½ years old, admitted to the surgical ward of the Children's Hospital March 17, 1900, supposed to be suffering from appendicitis and pneumonia, having been ill two days. The exact nature of the symptoms previous to admission is not recorded.

Examination on the 18th showed the abdominal walls tense and everywhere tender, especially on the right side, where the rigidity and tenderness were especially marked. The respiration was from 45 to 55, the pulse over 130 and the temperature from 103 to 104. Breathing appeared to be painful. Examination of the lungs showed slight impairment of resonance over the upper lobe of the left lung in front and of the lower lobe behind, yet nothing very characteristic or diagnostically positive was discovered. On the 19th the temperature was 103, the respiration from 40 to 50. The abdomen was distended and tympanitic, and the epigastrium and the region of the appendix were tender on pressure, and the left iliac region to a less extent. Abdominal pain was constantly present, but less than on the preceding day. The expression of the face was that of pain; herpes was present on the lips; the chest was tender everywhere on percussion. No change in the pulmonary condition is recorded. On the 20th the child was much brighter. The abdominal symptoms persisted, and physical signs of pneumonia of the right lung were very positive. By March 21 all abdominal symptoms had disappeared. There were now, how-

* Read before the New Jersey State Medical Society.

ever, evidences of some degree of pneumonia in both lungs, and the temperature was falling. By the 23d it was normal.

This case was puzzling, not so much to determine the presence of a pneumonia, which was suspected before admission, but because it was considered that the disease was occurring conjointly with appendicitis. Operation was considered when he first entered the surgical ward. I was asked to see him on the 19th or 20th, and determined positively the presence of pneumonia. Experience with the earlier cases made me believe that the abdominal symptoms were referred entirely from the lungs. The later course of the disease appeared to render this unquestionable.

CASE 4.—K. S., male, 7 years old, admitted to the Children's Hospital Nov. 2, 1899, under the care of Dr. H. R. Wharton. He had had at various times more or less abdominal pain, but never severe until three weeks previously, when he had a typical attack of appendicitis as regarded by the physicians in charge of him. The symptoms at the time consisted of severe pain and tenderness in the right side of the abdomen, especially at McBurney's point. fever, constipation and restlessness. He recovered partially, but the tenderness is said to have remained. On October 30, three days before admission, he had had a recurrence of pain, and again on November 1. There had been no vomiting at any time. Fever was said to have persisted since the attack three weeks before. On admission the temperature was 103, respiration varying from 32 to 80, and the pulse from 132 to 196. The abdomen was distended, tender and somewhat rigid. These symptoms were especially marked on the right side. There was also bronchial respiration over the entire lower lobe of the left lung. The attending physician had in person taken the child to the hospital in order to have an operation for appendicitis performed. On refusal by the surgeon to do this he became very angry, disputed the diagnosis of pneumonia, said he had brought the child for the sake of operation solely, and would remove him if it was not performed, and used other language more forceful than polite. He was requested to go to the ward to examine the patient himself again. This he did—and then apologized.

By the evening of the same day the temperature had fallen to 99.2. No further abdominal symptoms were recorded, and the pneumonic consolidation rapidly disappeared.

This case hardly needs comment. It shows how absolutely one may be deceived by the pseudo-appendicular symptoms unless careful study of other parts of the body is made.

CASE 5.—Walter E. C., 11 years old, admitted to the Children's Hospital to the service of Dr. Wharton on Nov. 25, 1901. He was taken ill November 22 with vomiting, headache and pain in the abdomen. The latter soon became localized at McBurney's point and continued until the 24th, being so severe that he lay awake crying during the night of the 23d. There was fever and the bowels were constipated. Two well-known physicians of Philadelphia, one of them a surgeon, had seen him and made the diagnosis of appendicitis. On examination in the hospital the temperature ranged from 103 to 104 or more, the respiration from 40 to 55 and the pulse from 95 to 130. There were no certain symptoms of appendicitis discoverable, but a well-developed croupous pneumonia of the base of the right lung was found, and he was transferred to the medical ward to the service of Dr. F. A. Packard. By this time the principal pain complained of had shifted to the right shoulder. There was also pain in the right side and in the epigastrium, but none had been present in the right iliac region since the evening of the 24th. The epigastric pain persisted until the 27th, when the temperature fell by crisis. After this date the pain grew less.

By the time the child reached the hospital the change in the locality of the pain had removed some of the difficulty in diagnosis. It is to be noted that the physical signs of pneumonia were developed at the time of entrance.

The next case is not so characteristic an example of the likeness of appendicular pneumonia to appendicitis. The child was admitted, it is true, for appendicitis, but this diagnosis was promptly corrected.

CASE 6.—Elmer W., 8 years old, admitted to the Children's Hospital May 8, 1900, in the service of Dr. F. A. Packard. He had wakened in the early morning of May 4 with fever and vomiting. Constipation, fever and cough continued from this date. For two days there had been pain in the right side. Examination showed the eyes sunken, the knees drawn up, the abdomen distended but not tender, frequent cough, temperature 103, respiration from 35 to 45, pulse from 140 to 170, pain in the right side of the thorax, and physical signs of pneumonic consolidation of the right lung. The temperature fell by crisis on the 9th.

The only suspicious symptoms in this case were the sunken eyes, distended abdomen and the drawing up of the legs, pointing toward abdominal disease. The diagnosis, however, was unattended by difficulty.

The following two cases were seen by Dr. H. R. Wharton in his private practice, and kindly submitted to me by him.

CASE 7.—Boy 15 years old, seen in consultation, a diagnosis of appendicitis having been made, and Dr. Wharton having been called for the purpose of operating. There were pain in the right iliac fossa and continued high temperature. Examination showed some rigidity of the right rectus muscle, and much tenderness on pressure in the region of the appendix. Further examination, however, showed consolidation of the right lung. The presence of appendicitis was excluded. The abdominal symptoms promptly disappeared, and the child passed through an ordinary case of croupous pneumonia, terminating in recovery.

CASE 8.—Boy 8 years old, who for nearly a week had had severe abdominal pain, particularly in the right iliac fossa. Dr. Wharton was called in consultation on the sixth day of the disease, the diagnosis of appendicitis having been made and operation being desired. The symptoms pointed to disease of the appendix, but it was noticed that the respiration was quite rapid. Examination of the chest revealed the presence of pleural effusion. This later became purulent and ruptured into a bronchus, the symptoms of appendicitis meantime having disappeared. Resection of the rib and drainage of the empyema was required later. Recovery followed.

Cases occurring in children and reported in recent literature have been multiplying so rapidly that I can give but the briefest synopsis of those which have come to my notice. There is no doubt that a careful search of the older literature would show more extended references to the condition, with illustrative cases, than is ordinarily supposed.

1. Fenwick (*Lancet,* 1893, Vol. ii, p. 79) reports 1 case.

Boy of 13 years was suddenly attacked with severe abdominal pain, vomiting and faintness after a long walk. In a few hours he became delirious. On the next day he was found to have fever, with a temperature of from 102 to 106, pulse 36, herpes on the lips, rapid respiration, occasional short, dry cough, considerable abdominal pain and tenderness and rigidity, especially in the umbilical and left lumbar regions. The legs were drawn up in bed. Nothing abnormal was discovered in the chest. Vomiting continued troublesome, and the delirium gave place to stupor. On the third day all the symptoms improved greatly, and dulness at the left base behind, with impairment of the respiratory murmur, was discovered. Improvement continued, and the abdominal tenderness disappeared to a large extent. The temperature reached normal in three days. Later, pleural effusion was found.

Four other cases were reported, all in adults. In all the symptoms pointed distinctly toward inflammation in the abdomen, but the disease appeared to be dia-

phragmatic pleurisy. In two of the cases pleural effusion developed. In another the autopsy showed extensive involvement of the diaphragmatic pleura.

2. Morse (*Annals of Gynec. and Pediat.,* 1897) reports 3 cases.

(A) Boy of 7 years. A blow in the abdomen was followed soon by faintness, nausea and vomiting. The next day nausea, headache, pain in the abdomen, constipation, slight fever and slight abdominal distension and tenderness developed. Examination of the lungs was negative. The abdominal pain and tenderness increased, especially in the right iliac region, with slight dulness there. Respiration and pulse were rapid, the temperature was high, and there was a constant hacking cough. Appendicitis was suspected. On the fourth day of the attack physical signs of pneumonia were well marked over the right lower lobe, the abdominal symptoms disappearing.

(B) Boy of 8 years had headache, slight abdominal distension and tenderness, constipation, rapid respiration and a temperature of 105. Nothing was found in the lungs. Vomiting occurred in the night, and on the next day there was slight cough and the abdomen was much distended and tender, especially on the right side. The examination of the lungs was still negative. Up to the sixth day of the disease the condition was the same. On this date the respiration became more rapid and painful, the cough increased, pain in the chest developed, physical signs of pneumonia of the right lower and middle lobes were found, and all abdominal signs disappeared.

(C) Girl of 3 years, taken ill suddenly with fever and abdominal pain. On the next day she vomited, had continued abdominal pain, but no cough. Seen thirty-six hours after the onset, the temperature was found to be 39.9 C., the respiration and pulse rapid, but nothing abnormal was found in the lungs. On the fourth day of the attack solidification of the left lower lobe was discovered.

Morse considers the occurrence of pneumonia with initial abdominal symptoms not uncommon. He says that the abdomen has been twice opened for appendicitis in children within the past few years by prominent surgeons in Boston when the trouble was really pneumonia. He believes that the sudden onset with high fever and rapid respiration should suggest pneumonia, even in the presence of abdominal symptoms and the absence of cough.

3. Guinon (*Bull. de la Soc. de Paris.,* 1901, p. 77) reports one case.

Girl of 13½ years, had had fever, headache and pain in the right side of the chest for about eight days before admission to the hospital. On the day after admission she exhibited an anxious expression of face, sunken eyes, pain in the right side of the abdomen with tenderness at McBurney's point, little cough, no dyspnea, no physical signs in the chest. The case was supposed to be appendicitis, but firm pressure with the flat of the hand showed no tenderness and no increased resistance, although sudden pressure with the finger-tip gave pain. For two days more the diagnosis remained uncertain, pain persisted and positive signs of pneumonia were found at the right apex. The temperature fell by crisis in the evening, and on the next day the abdominal symptoms disappeared and the physical signs of pneumonia throughout the right lung were positive.

4. Massalongo (*Riforma Medica,* 1901, 711) says that he has observed 4 cases in children of from 5 to 12 years in which pneumonia simulated appendicitis. He recalls 5 cases in which operation for appendicitis was done and the organ found entirely sound, the real disease being pneumonia.

He calls the condition pseudo-appendicular pneumonia and dwells on the difficulty in diagnosis which lasts until after the third or fourth day, by which time the abdominal symptoms lessen and the physical signs of pneumonia are liable to be detected. The pain is projected by way of the sympathetic and the spinal cord to the twelfth intercostal nerve.

5. Richardson (*Boston Med, and Surg. Jour.*-1901, April 17, p. 399) reports 5 cases in children.

(A.) Boy of 6 years, had for three days right lumbar pain, persistent vomiting and headache. On the third day a tense abdomen and right iliac tenderness were found, and the temperature was 105.5: On the fifth day the respiration was 40, the abdomen distended, the legs drawn up, the eyes sunken, and the general appearance bad. A diagnosis of appendicitis was made. On the sixth day the appendix was removed, but nothing of moment was found. Dyspnea and cough then developed, followed by empyema. He says that the case was one of pleurisy simulating appendicitis.

(B.) Boy 4 years old. On the second day there was abdominal pain, cough, and a temperature of 101, and appendicitis was thought of. On the third day pneumonia of the left lung was suspected. There was much pain in the epigastrium and in the left shoulder; the respiration was 42 and the temperature 105. On the fifth day symptoms suggestive of pneumonia, but not positive, were found. On the sixth day there was acute abdominal pain, constant in the region of the appendix. The abdomen was distended but not hard, with dulness in the right iliac region. The pain lasted several days and then disappeared. The final diagnosis was pneumonia of the left lung.

(C.) Girl, 5 years old, suddenly developed abdominal pain, which continued on the next day chiefly in the right iliac fossa, with a temperature of 104.4. Fever and pain diminished after ten days, but a little tenderness remained somewhat longer. About a week later pain and fever returned, appendicitis was thought of, and Dr. Richardson was summoned to operate. He found pneumonia of the right lung and tenderness along the course of the lower intercostal nerves. There had been no suspicion of the existence of pneumonia.

(D.) Boy of 4 years was attacked by cough, restlessness, fever, accelerated respiration, constipation and slight distension of abdomen. Nothing abnormal was found in the lungs. The condition continued, and on the eighth day the child developed abdominal pain, great tenderness over McBurney's point, and rapid respiration. Dr. Richardson was called in on the ninth day on account of suspected appendicitis. He found vomiting, severe abdominal pain, tenderness in the right iliac fossa, distension, but no rigidity. Operation was deferred. On the tenth day pneumonia was discovered, and the abdominal symptoms disappeared rapidly.

(E.) Girl of 7 years had had abdominal pain, fever, rapid respiration and cough for two days. On the third day the cough ceased, and on the fourth day severe abdominal pain developed, which disappeared, but left abdominal tenderness. Appendicitis and peritonitis were suspected. Examination on the fifth day showed tenderness over the appendix, no abdominal rigidity, a temperature of 104 to 105, and respiration of 40. The diagnosis was very uncertain, and operation was delayed. Signs of pneumonia were found the same evening.

Richardson also describes a case in an adult male brought to the hospital for abdominal operation. In a few days pneumonia was found.

He says that in acute right-sided diseases of the thorax the symptoms of appendicitis may be so simulated that a surgeon may be completely deceived. It was only his experience in the first case which kept him from operation in the others. The high temperature and rapid respiration are the most assuring symptoms.

6. Hampeln (*Zeitschr. f. Klin. Med.* 1902, 448) reports 5 cases, all in young adults and showing the most typical symptoms of sudden acute abdominal conditions. Collapse was present in some. In all the symptoms simulated peritonitis or intestinal occlusion.

7. Satullo (*Gaz. degli Ospedali,* 1902, xxiii, 757) reports 3 cases, all in adults. In all there was severe

pain in the right iliac fossa with an exceptionally high temperature, running from 43 to 44 C. at the maximum. It was only after several days of observation that the diagnosis of pneumonia was possible. Satullo designates the condition appendicular pneumonia, and says that pneumonia may begin with symptoms of acute appendicitis and the diagnosis be uncertain for three or four days. Pain at McBurney's point is reflex and is transmitted along the anterior branches of the twelfth intercostal nerve.

8. Barnard (*Transac. Clin. Soc. Lond.*, 1902, xxxv, 122) reports 2 cases in children.

(A). Girl of 11 years, had had some abdominal pain with vomiting during three days. When seen on the fourth day the temperature was 103.6, the respiration 40 and painful; there was tenderness in the right iliac fossa, abdominal rigidity, and constipation. Four days after admission obscure signs of pneumonia of the right base were found. The temperature fell by crisis this day, but rose again, and signs of diaphragmatic pleurisy developed.

(B.) Boy 10 years old, had been ill for two days with abdominal pain and vomiting, following a blow on the abdomen and the lower part of the chest. He was admitted to the hospital for acute traumatic peritonitis. Examination showed the abdomen distended, rigid, tender; the legs drawn up; constipation; a temperature of 99.5, soon rising to 103; the respiration 44, and the throat negative. On the next day undoubted signs of pleuro-pneumonia of the right base were found. Empyema developed later.

Four other cases are reported; one in a girl of 17 and three in men, in which severe abdominal symptoms were produced by pneumonia or pleurisy. In the case of the girl the diagnosis of perforating gastric ulcer had been made, and operation was performed, but no signs of this condition were found. On the next day physical signs of pneumonia of the right base were found. In the case of one of the men operation was performed for supposed laceration of the spleen from trauma, the symptoms being due in reality to a traumatic pleurisy of the left side. The two other cases exhibited symptoms of peritonitis dependent on the presence of pyopneumothorax.

Barnard refers to the fact that the older writers recognized the simulation of abdominal diseases by pneumonia or pleurisy. He speaks of cases reported by Andral and Fagge. He says that the relaxation of the abdominal walls with each inspiration, the rapid respiration, the absence of weak or irregular pulse, the fact that the tenderness is superficial and disappears under firm pressure by the flat of the hand, and the sudden high elevation of temperature speak against peritonitis and for pulmonary disease.

9. Comby and Zielinski (*Arch. de Med. des Enf.* 1902, 741) report 1 case.

Boy of 8 years was attacked suddenly by vomiting, abdominal pain, constipation and fever. On the next day there was a temperature of 39.3 C., an anxious expression of face, pain and tenderness on the right side of the abdomen, no cough, and nothing abnormal in the lungs. On the fourth day vomiting and distension of the abdomen developed. Appendicitis was thought of, but beginning physical signs of pneumonia of the right side were found. Crisis occurred on the seventh day.

The writers caution against an early diagnosis based on what appear to be appendicular symptoms. There should be increased muscular resistance and deep induration to justify the diagnosis of appendicitis.

10. Cozzolino (*Gaz. degli Ospedali*, 1903, xxiv, 45) reports 1 case.

Girl of 3 years was suddenly attacked by high fever, severe abdominal pain, especially on the right side, vomiting and anorexia. Examination on this day showed the child lying on the right side with thighs strongly flexed, great abdominal tenderness and pain, temperature of 39.7 C., pulse 150, rapid respiration, slight dyspnea, dry cough and constipation. She vomited during the examination. Practically nothing abnormal was found in the lungs. After much persuasion palpation of the abdomen was permitted; firm, steady pressure with the palm overcame the muscular contraction, and nothing abnormal was found at McBurney's point. On the next day the pain was slightly less; the cough little worse, and vomiting had ceased, and in the evening characteristic signs of beginning pneumonia of the right base were discovered. Abdominal pain slowly diminished, and disappeared by the sixth day.

He believes that pressure with the flat of the hand is a valuable aid in diagnosis, and dwells on the caution to be exercised in basing an opinion on the ordinary train of symptoms of appendicitis.

It is not necessary to review much further the individual cases or the general observations of the different writers as already quoted. There is evident a decided uniformity in most of the statements. They are in entire accord, too, with what the new cases I have reported show. There is, namely, especially in early life, a well-recognized, long-known, but frequently forgotten, tendency for patients with pneumonia or pleurisy to refer to the abdomen the pain really produced in the chest. This is more liable to happen when the disease is situated in the lower part of the thorax, but there is reason to believe that it may also occur when it has attacked the upper portion. It is also more deceptive when the right side of the thorax is affected, since the right side of the abdomen is then liable to exhibit pain, and the presence of appendicitis is suggested. Combined with the abdominal pain in these cases there is also constipation and abdominal tenderness and distension. These symptoms, together with the vomiting which quite commonly ushers in an attack of pneumonia in childhood, easily produce a clinical picture very closely simulating that of appendicitis.

The distinction is to be made by giving due consideration to (1) the sudden rise of temperature to 103 F. or thereabouts, and the tendency to maintain this degree; (2) the acceleration of respiration, which is out of proportion to the pulse rate or the pyrexia; (3) the relaxation of the abdominal walls between the respirations; (4) the diminution or the disappearance of tenderness on deep pressure with the flat of the hand; (5) the possible presence of cough. Finally, no operation for appendicitis should ever be performed until after a careful, or perhaps repeated, examination of the lungs has been made. All these points will, however, frequently fail to make the diagnosis certain, as the experience of some of the able observers quoted has shown.

Ozena of the Bronchi.—Béclère of Paris has observed several cases of a chronic bronchial affection similar to ozena of the nose. In some cases it was consecutive to measles, whooping cough or influenza, in others it was secondary to nasal ozena. In the majority the nasal passages were normal. All were improved or completely cured by intratracheal injections of peroxid of hydrogen and mentholized oil. Unilateral sclerosis of the lung with dilatation of the bronchi is the usual basis for the affection, as can be determined by radioscopy. If the latter is neglected the symptoms may suggest the erroneous diagnosis of a recurring vomica. The *Bull. Soc. Méd. des Hop.*, for June 25, contains Béclère's communication on the subject.

ABDOMINAL PAIN IN PLEURISY AND PNEUMONIA.*

JAMES B. HERRICK, M.D.
CHICAGO.

That a disease in one part of the body may call forth painful sensation in another part is a matter of every-day observation. Pain in the knee may mean hip-joint disease; the passage of a renal calculus may make pain in the testicle or penis; a gallstone may cause pain referred to the neighborhood of the right scapula; pain in the neck or left arm and hand may indicate angina pectoris and coronary sclerosis. While in pleurisy and pneumonia the pain is usually referred to the chest and to the side affected, it may be referred to points remote from the site of the disease, as to the opposite side or to the abdomen. This fact had not escaped the keen observation of our forefathers in clinical medicine. Laennec[1] speaks of the pain of pleurisy as sometimes shifting its place and "occasionally," he says, "from the beginning of the disease, we have a stitch on the right side and pleurisy on the left." Gerhardt also reports this fact. Huss[2] treated of this subject, explaining the pain on the other side by the occasional anastomosis of right and left intercostal nerves. Barnard,[3] who has lately written of abdominal pain in pleuropneumonic diseases, cites Andral, Watson and Fagge as clearly recognizing the fact that severe abdominal pain might have its origin in the pleura, and be misleading unless care were exercised in the physical examination. While several articles have lately called attention to the danger of confusing pulmonary and pleural diseases with peritoneal, this danger is not touched upon by many writers on diseases of the chest or abdomen, nor has it among practitioners of medicine and surgery the general recognition that it deserves. But the subject is well worth emphasizing. For in these days, when even the recent graduate stands ready to attack the appendix of every individual the moment there is right iliac pain, tenderness and rigidity, with fever, the seriousness of a mistake in diagnosis in a case of this sort is plain. This, then, is my excuse for presenting a subject that is not new.

The lower six intercostal nerves—the anterior divisions of the dorsal nerves—supply the abdominal wall, as well as a part of the parietal and diaphragmatic pleura. An irritation, e. g., from inflammation or pressure, in the course of one of these nerves might readily cause a pain that would be referred to the distribution of this nerve, i. e., to the abdominal wall. In cases of pleurisy how much of the irritation is produced by true neuritis is, perhaps, uncertain. By many intercostal neuritis is regarded as of common occurrence in pneumonia and pleurisy.[4] The eleventh nerve is distributed over the iliac region. Pain here would easily make one think of the appendix if on the right side, or if on the left, perhaps of the rarer left-sided appendicular pains. The other nerves would cause pain referred to the umbilical, epigastric or hypochondriac regions and the confusion that might result when we think of the possible significance of such pain in the way of ulcer of the stomach, gall bladder mischief, pancreatitis, etc., is clearly seen.

This close anatomic nerve connection between the abdominal wall, the pleura and the intercostal muscles is indicative of a physiologically intimate relationship, clearly seen in the common function of the thoracic and abdominal muscles in the act of respiration. Hilton's well-known law declares that the interior of a joint, the muscles moving it and the skin over the muscular insertions are supplied by the same nerve trunks. This law also applies to the pleura, which, he says, can be compared to a joint. And the muscles to be regarded as moving the joint are not alone the intercostals, but the abdominal as well.[5] Not only may pain of pleural origin be referred to the abdomen, but in their effort to lessen pain and to give the joint, i. e., the pleura, rest, the muscles remain quiet and may even be tense. One can readily understand how the tenseness of abdominal muscles, added to pain, may be deceptive because of the close resemblance to the phenomena of abdominal disease. And how strikingly like the picture of abdominal inflammation may be the combination of pain and rigidity when chilliness, fever, rapid pulse, etc., are also present.

There is still another possible explanation of some of the abdominal disturbances that are seen in pleurisy and pneumonia. The phrenic nerve in its course through the chest lays itself open to the attack of a pleurisy involving the pericardial, diaphragmatic or costal surfaces. This nerve is not solely motor. Henle, Luschka and others regard it as a mixed nerve. Van Gehuchten[6] says that in its course it gives off sensory fibers to the pericardium and to the pericardial, costal and diaphragmatic pleura, its terminal filaments furnishing sensation to the peritoneum covering the interior surface of the diaphragm.

Irritation or inflammation of this nerve, as in pleurisy, may perhaps be an explanation of some of the cardiac and gastric disturbances, the collapse and meteorism because the phrenic has communication with the vagus and the splanchnics. The halting movement of the diaphragm, as well as pain referred to the epigastrium and hypochondrium, may likewise be due to phrenic disturbance. Hampeln[7] advocates this view quite strongly, overlooking too much, as it seems to me, the part played by the intercostals in the production of abdominal pain.

It is not necessary to assume in cases of this sort that the inflammation is in the diaphragmatic pleura, i. e., in the part of the pleura anatomically nearest to the abdomen, though undoubtedly this part of the pleura is often inflamed. Rohrer[8] calls attention to the frequent occurrence of inflammation of the diaphragm itself, and believes that to this is due in part the stitch pain, as well as the pain in the abdomen often complained of, especially in children.

Head,[9] who has done so much to explain referred visceral pain, believes that in certain cases there may be abdominal pain when the lung alone is involved without the pleura, e. g., in bronchitis, tuberculosis or bronchopneumonia. He says that through the communicating branches of the seventh, eighth and ninth dorsal nerves, which branches supply the lungs, impulses originating perhaps in a small inflammatory pulmonary focus may be carried up to the posterior root ganglia. From the abdominal wall normal impulses pass from the epigastric

and hypochondriac regions to these same ganglia. If, through the abnormal impulse coming from the lung, the ganglia have become disturbed in their function, the normal impulses from the abdomen may be distorted, i. e., misinterpreted, into painful impressions. Head tells Barnard (loc. cit.) that he has seen cases of this sort.

Whatever may be the correct explanation of this abdominal reference of the pain in thoracic disease, the fact that such pain may occur should be clearly recognized by both physician and surgeon. While infrequent, it is more than a curiosity, and it is not so rare that it does not deserve a place in the symptomatology of these diseases.

ILLUSTRATIVE CASES.

I wish by brief reference to cases that have come under my observation, and then by reference to the experience of others, to show that this pain may occur, that it may be a misleading symptom, but that by care it generally permits of a correct interpretation.

In the pneumonia of children abdominal pain is common. The sudden onset with severe pain, fever and vomiting, with the tenderness and distension of the abdomen, make the resemblance to local or general peritonitis striking.

A year and a half ago I was called by two physicians to see a child of three to decide as to the advisability of operation for appendicitis. The history was, as I have stated, sudden abdominal pain, vomiting, high fever, tympanitic and tense abdomen. Yet the cough, expiratory grunt and rapid respiration were plain, as were the physical signs of consolidation of the left lower lobe. Later a pneumococcus empyema developed, healing under drainage.

In this case, as so often happens to us all, the attention had been riveted on the part of the body in which the brusque initial symptoms had appeared, and the later symptoms of trouble in another part of the body, though plain to one new to the case, were thus overlooked.

The lobe involved to produce this pain is not necessarily the lower lobe.

Feb. 22, 1902, I saw with Dr. Klein, a girl of seven years, whose pneumonia began with vomiting, pain and tenderness in the right iliac region, temperature 103, and in whom Dr. Klein found the next morning signs of consolidation of the right upper lobe. A typical pneumonia with high fever, 106, and migration to the middle lobe followed. At the time I saw her the upper and middle lobes alone were solidified.

The same abdominal pain in a left upper lobe pneumonia was present in a 6-year-old child seen with Dr. B. H. Chamberlin, March 12, 1902. The mother described it as "cramps in the bowels." In these upper lobe cases the explanation of the reference of the pain to the abdomen may be that of Head, of Hampeln, i. e., through the phrenic nerve, or that the pleurisy and accompanying neuritis may be more extensive than the anatomic boundaries of the lobe that is solid, i. e., may involve the lower intercostal nerves.

While in conversation with physicians, I have found some who expressed surprise at, or even unbelief in the onset of pneumonia with sharp abdominal symptoms. I have found many who regard abdominal pain as an important early symptom of pneumonia in children. Some writers on pediatrics are silent regarding that point. Others clearly recognize it, e. g., Baginsky, Henoch, DeMussy and Bouveret. Holt[10] refers explicitly to it in the following words:

The pain is frequently referred to the loin, the epigastrium or to any region to which the intercostal nerves are distributed.

In a recent case, in a boy of seven years, for the first twelve hours there was intense localized pain in the right iliac fossa, associated with such extreme tenderness as to lead to the suspicion that the case was one of appendicitis.

This will be the proper place, I think, to say a few words concerning pleurisy and pneumonia, coincident with or following abdominal disease. Coincident with or following an appendicitis, a pneumonia or pleurisy may appear, the abdominal and thoracic disease both due to the same cause, e. g., the pneumococcus, or the one being secondary to the other. Gussenbauer showed that from thrombosed veins accompanying intestinal obstruction embolic pneumonic foci could appear in the lung. And lately Sonnenburg[11] has fully discussed the similar embolic origin of pneumonia met with during appendicitis, before or after operation. These cases in which the abdominal pain is accompanied by, and probably due to, definite abdominal disease, do not properly belong in the category of those I am considering. But I mention them as in a given case the possibility of the coexistence of both abdominal and thoracic disease must always be kept clearly in mind, a condition not at all infrequent in tuberculosis, carcinoma or general septicemia.

A few months ago I was called to see a girl of about five years, who was regarded as in too weak and desperate a condition to undergo an operation for appendicitis and peritonitis, from which she was said to be suffering. The case was certainly a puzzling one. I was able to demonstrate clearly an extensive consolidation of the lower right lobe and a portion of the lower left. This had not been overlooked by the physicians. The respiration, temperature, mental condition were suitable for pneumonia. But a severe initial and continuous abdominal pain, a rigid, somewhat tympanitic abdomen and a persistent vomiting made the peritonitis seem probable. Yet careful inquiry into the history showed that within 12 hours of the onset the respiration rate had been 52. Palpation also led me to question the existence of a peritonitis, for with care, and by gentle, steady pressure, it seemed to me that there was less tenderness and less real rigidity than were consistent with the supposed extensive peritonitis. This case, illustrated too, I believe, the truth of Barnard's observation that there is a yielding or softening of the abdominal wall at the beginning of each inspiration in these cases where the pain is of thoracic origin. Medicine and food by the stomach being stopped for a few hours, and opium given, the vomiting ceased. There was in a few days a marked improvement in all respects. But convalescence was slow, with some cough, dullness and râles and signs of delayed resolution. No pus was found by a needle in a suspicious area in the right chest. During this convalescence, for a few days the patient had a distinct rigidity of the lower abdominal wall. A complete recovery ensued, the illness lasting altogether about seven or eight weeks.

I am inclined to regard the case as primarily and even solely pneumonic. Yet it is possible that there was here a simultaneous infection of the lung and peritoneum, or the peritoneum may have been involved after the lung, or vice versa. The slow convalescence with persistent abdominal pain was present in one of Richardson's cases.

Turning now to adults, we find that they may exhibit, though less frequently, the same abdominal pain with pleurisy or pneumonia, and this may simulate a peritonitis.

A young man of about twenty, with sudden abdominal pain and fever had some rigidity in the right iliac region. His physician with whom I saw the case found here a mass concerning whose exact nature he was somewhat in doubt. The possibility of appendicitis was naturally thought of. But he gave a dose of calomel, the mass disappeared, and in twenty-four hours a right lower lobe pneumonia was clearly made out.

11. Sonnenburg: Lungencomplicationen bei Appendicitis, Archiv. für Klinische Chirurgie, Bd. lxviii, p. 468.

I once showed a man in a clinic at the County Hospital with right iliac pain and marked friction rubs over the right chest. He had escaped an operation for supposed appendicitis only because he refused to permit it. Several times patients have been sent to the surgical wards from the examining room with the diagnosis of appendicitis when the more careful ward examination by the surgeon has shown the case to be pneumonia. I know of an instance in Chicago where the abdomen was opened for supposed appendicitis, when the whole trouble was a pneumonia unrecognized at the time of the operation, but which had caused symptoms that were regarded as those of appendicitis. I could cite several other cases in which abdominal pain has been a prominent feature in cases of pleurisy and pneumonia sometimes leading to perplexity as to the correct diagnosis. Thus a woman of 37 years with right pleural effusion told me that her trouble began twenty days before with a pain in the "stomach and side." In another case severe pain just above the crest of the ilium was present for two days before definite physical signs of pneumonia were present.

Dr. Bevan, in October, 1901, operated for me on a patient with acute appendicitis, draining a small abscess due to gangrenous perforation of the appendix. There was a slow but apparently complete recovery. From April to June, 1902, the patient was at her work as a nurse. About June 15, 1902, she had pain in the right chest, temperature 99 to 100. To this she paid little attention, but she became greatly alarmed when she had pain in the old region, i. e., at the site of the scar of the operation. Neither Dr. Bevan nor I could find local evidence for suspecting any recurrence of trouble in the region of the appendix. We thought the pain was referred from the chest in which could be clearly made out a pleural friction and the signs of a small amount of fluid. Within a few days all abdominal symptoms cleared up.

Still another case I may mention. A young lady with a large carbuncle of the upper lip, and with the grave constitutional symptoms attending it—the condition is, as is well known, generally due to the staphylococcus and often fatal—developed a severe pain in the right chest. In the latter location a friction rub with a fine crackling râle and a patch of harsh respiration could be made out. Nothing but the pain over the region of the appendix could be found suggestive of appendicitis, at least to Dr. N. S. Davis, Jr., and myself, who both saw the patient several times, though to some the probability of appendicitis seemed strong. The embolic pneumonic focus was evidently the explanation of the pain. There was ultimate recovery, the later history proving no appendicitis.

Twice I have seen pain referred very accurately to the region of the gall bladder, and the patients in both instances were sure there was cholecystitis, a natural interpretation, perhaps, when we consider that the one patient was a medical student and the other a physician, noted for being poor judges of their own ailments. The student had a right-sided pleurisy. The physician, in addition to the pain, had fever, local tenderness, and was jaundiced. He naturally concluded that he had gallstones and cholecystitis, though the whole trouble was clearly, as the sequel proved, a right lower pneumonia. In this case the pain was pretty definitely located at the point where the tenth rib joins the costal arch, close to the crossing of the parasternal line and the tenth rib, the *bouton diaphragmatique* of some writers. It should be regarded as suggestive of pleurisy, especially of the diaphragm, when this spot is the seat of pain or tenderness upon pressure.[12]

A patient whom I saw with Dr. F. S. Hartmann, was, after nearly two weeks, convalescing from an acute rheumatism and alcoholism when he was seized with a sudden excruciating pain in the upper left quadrant of the abdomen. Dr. Hartmann found him tender to pressure in the left hypochondrium; he soon vomited and became tympanitic. He did not, however, go into collapse immediately after the onset of the pain, and there was no marked perturbation of temperature. Three days later when I saw him, the tympany was less, the vomiting persisted and was grumous, there was an extensive pleurisy to be made out over the left chest, with a dullness and harsh breathing suggestive of pneumonia. The patient was rapidly failing, and died a few hours later. While no positive diagnosis was ventured by either Dr. Hartmann or myself, we both looked on the pleurisy as probably secondary to some subdiaphragmatic lesion—perhaps hemorrhagic pancreatitis or localized peritonitis from an ulcer of the stomach.

The autopsy made the next morning by Dr. H. G. Wells revealed nothing in the abdomen to explain the symptoms except a high grade of gastritis with submucous ecchymoses. Capillary oozing explained the blood in the vomitus. The left pleura was, however, the seat of an acute inflammation especially well marked over the diaphragm. The lung was edematous and congested with several hemorrhagic areas the size of a hickory nut. The blood showed a pure growth of a bacillus of the colon-typhoid group. Its exact nature was not discovered owing to an accident to the cultures, though the study of the organism as far as carried out made it seem probable that it was the typhoid bacillus.

Here was a case where the diagnosis should read as follows: Acute alcoholism, acute inflammatory rheumatism, typhoid (?) bacteriemia, acute pleurisy involving the diaphragm.

These cases will illustrate, I think, the importance of this occasional symptom of thoracic disease. That my experience is not unique I know from conversation with other physicians, and a few illustrative citations from the writings of others will be convincing on this point. Janeway[13] says he has several times been consulted in cases of pleurisy or pneumonia, where, because of the neuralgic pains reflected over the lower right abdomen, there has been entertained the idea of an operation for appendicitis. Osler[14] says that twice in cases of pneumonia he has seen the suspicion of appendicitis raised because of the sudden acute onset of the pain, once in the region of the navel, and once lower down on the right side. In discussing typhoid perforation, he[15] says: "Abdominal pain of a severe character in typhoid fever may be associated with an acute pleurisy."

This abdominal pain due to pleurisy I once saw in a typhoid. Because of its sudden occurrence and because of a sudden jump in the leucocytes my interne had naturally suspected perforation. Yet an absence of rigidity and of local tenderness and the presence of a fine pleural friction, with harsh localized breath sounds, led me to wait, and the autopsy two days later showed no perforation, but a bronchopneumonia.

Fraentzel[16] saw two cases of pleurisy that closely resembled peritonitis.

Cozzolino[17] refers to four cases reported by Massalongo last year in which cases of abdominal pain in children had aroused suspicion of peritonitis, though the trouble was intrathoracic. Cozzolino's own case was in a child of three years with symptoms like those of appendicitis, including tenderness over McBurney's point, though palpation that was *"dolce, lenta, graduale"* showed little

pain and no induration. Next day pneumonia was plain. Guinon[18] also in his case found that gentle pressure with the flat hand and not the finger revealed less tenderness and less resistance than the previous complaint of the patient, a 13-year-old girl, would indicate.

Morse[19] reports three cases in children, one of which was called appendicitis and another gastritis, though pneumonia was in each case, as the later history showed, the cause of the abdominal symptoms. He says: "Within a few years the abdomen has twice been opened in children by well-known Boston surgeons for appendicitis when the trouble was lobar pneumonia."

Brewer[20] reports an operation for appendicitis in a woman 30 years old, the abdominal pain, more or less general abdominal tenderness, slight muscular rigidity and distention, with leucocytosis, leading to this diagnosis. The abdomen was opened, but no sign of inflammation was anywhere discovered. The examination of the chest a few days later revealed a circumscribed pneumonia of the right lung, though prior to the operation there were no abnormal chest findings. Two weeks later and after the fever had subsided a small abscess immediately beneath the anterior abdominal wall of the left side, was opened. Brewer thinks that the pneumonic focus had induced the early abdominal symptoms.

He cites another case. A man convalescent from an acute lobar pneumonia, after being free from fever for six days, complained of pain in the right iliac region, vomited and developed fever. As he had years before had what was called appendicitis, a recurrence was naturally suspected. Muscular rigidity and tenderness became marked, the temperature rose, tympanites was extreme and the diagnosis of peritonitis was concurred in by Drs. Janeway, Bull and Brewer, who saw the patient with his physician, Dr. Evans. Because of the desperate condition of the patient an operation was regarded as inadvisable. The autopsy showed a normal peritoneum, a resolving pneumonia of the lower lobe of the right lung, a pneumococcus septicemia. How much of the abdominal pain and other symptoms were due to the pneumonic trouble and how much to the septicemia, it is impossible to say. Yet I cite the case here as an instructive one, and as showing the ease with which peritonitis can be simulated by other conditions.

Barnard's six cases in which abdominal symptoms were prominent, though no abdominal disease was present, deserve to be quoted in full, but lack of time will prevent this. Three were cases of pleuropneumonia involving the base of the lung. In two a pyo-pneumothorax developed, in each case apparently from rupture of a tuberculous focus in the apex of the lower lobe. One was a traumatic pleurisy with broken ribs. In this case the pleurisy was plainly recognized, but so definite were the abdominal signs that the abdomen was opened and found entirely normal.

The most interesting of these cases and one which, as Barnard says, was a most perplexing one, concerned a chlorotic girl of seventeen under treatment for ulcer of the stomach. A sudden violent epigastric pain, vomiting, collapse, rapid pulse, temperature 104.5 F., a tender abdomen, especially in the epigastric region, led to an almost immediate operation for perforated gastric ulcer. Nothing of the sort was found. On the second day after admission a right basal pneumonia was clearly made out, later also in the left base. The autopsy showed double basal pneumonia and right diaphragmatic pleurisy and "in the stomach a shallow ulcer of the size of a sixpenny piece, which was not even near perforation. There was no peritonitis." Surely this was a hard case to diagnose. As Barnard says, the sudden rise of temperature should have excited suspicion of somethinng else than perforation.

Hampeln's five cases are also worthy of careful study, he dwelling not only upon the possible misleading character of the referred pain, but upon the vomiting, tympany, collapse, etc., that he explains on the theory of disturbance of the phrenic nerve with secondary disorder of the vagus and splanchnics. Surgical intervention in some of these cases was narrowly escaped, and only because Hampeln's experience had led him to examine with unusual care for thoracic trouble. Hampeln's cases were, to quote his own résumé, "two fatal cases of foudroyant pleurisy with recovery, one fatal and one favorable case of croupous pneumonia, all in the beginning of the illness, creating the impression of a peritonitis or intestinal obstruction, while the ordinary marks of the real disease were absent, and even the physical examination, at least at the beginning, was negative." (loc. cit., p. 450.)

Dr. M. H. Richardson[21] discusses in a very frank manner the possibility of mistaking acute thoracic disease for appendicitis, citing instructive cases. He makes out the error in diagnosis as often due to the fixation of the thought of the observer on the one part of the body or on the one disease. Arguing from a psychologic standpoint, he says:

For a true perception of the normal relation of things to be temporarily suspended, it is only necessary that the mind for the moment be dominated by a fixed idea. Influenced by a single suggestion or by a chain of suggestive circumstances, the mind may become so possessed of a certain idea that the result will necessarily be distorted and incorrect.

How true this is we all know to our sorrow, in more than single instances. I referred to this point in speaking of the child on whom operation was contemplated for appendicitis. The minds of the two physicians had, as Richardson says, become dominated by the fixed idea of appendicitis, though pneumonia was plainly recognized by both as soon as the possibility of its existence was pointed out. Barnard says the opinion that in his case of traumatic pleurisy there were abdominal complications was largely due to the fact that a few weeks before, with a somewhat similar injury and symptoms, there had been rupture of the spleen with hemorrhage. His mind was drawn, therefore, toward the possibility of a duplicate of this somewhat rare occurrence.

CONCLUSION.

There is little to say in conclusion. Cases may occur in which at first it may be impossible to say whether the trouble is abdominal or thoracic. Each case must be judged on its own merits, and the decision as to immediate operation or waiting, not settled by any hard or fast rule. Certainly in some doubtful cases with threatening abdominal symptoms, it would be better to err on the side of operation and make a laparotomy than to let a possible ruptured appendix, gall bladder, stomach or intestine go untreated for six or twelve hours. An exploratory abdominal incision could, perhaps, be made under local anesthesia or under laughing gas. This would avoid the danger of adding bronchitis, or aspiration pneumonia to an already existing pulmonary inflammation, if such happened to be the primary trouble and the peritoneum is found normal. If peritoneal trouble is found ether or chloroform anesthesia can be added and the reparative surgical procedure instituted.

But with care and circumspection doubt will seldom arise. The main safeguard in the diagnosis is to think of the possibility of a thoracic origin for the abdominal

symptoms. It will then be generally found that there is some thoracic pain, as well as abdominal, or there will be cough or expiratory grunt, perhaps a bloody or rusty expectoration, or the respiration will be increased out of all proportion to the abdominal pain and tympany, or, as in Barnard's case, the temperature will rise too suddenly and too high for the supposed abdominal accident. These facts, if observed, will lead one to a careful examination of the chest, which will, in most instances, even early, reveal some loss of motion, friction, râle, dullness or bronchial breathing that discloses the existence of an intrathoracic inflammatory condition, and makes it clear that the abdominal pain is a reflected one. The abdomen in these cases is often pseudo-tender. A light touch hurts. Quiet, steady, deep palpation with the flat hand does not increase the pain. And, as Barnard observes, at the beginning of inspiration there is a yielding of the abdominal wall that is seldom seen in true peritonitis. With care, then, most of these cases can be recognized. I need not repeat what I said at the beginning, that this recognition is important. That truth is self-evident.

I may add that in this paper I have made no reference to other reflections of the pain of pleurisy and pneumonia, e. g., to the neck or to the lumbar region. Nor have I thought it wise to extend the scope of the paper so as to include such thoracic diseases as pericarditis, aneurisms, tumors, vertebral tuberculosis, etc. I have purposely limited myself to a consideration of the abdominal symptoms, chiefly pain, in acute pleurisy and pneumonia, believing that this is the form oftenest overlooked or misinterpreted.

DISCUSSION.

Dr. J. N. Hall, Denver—There are many points of confusion that I do not think Dr. Herrick has touched. I once saw the daughter of a member of our Association concerning whom two physicians and surgeons were in doubt regarding the presence of appendicitis or pneumonia. It proved to be the former. Confusion existed because there was abdominal distension, the liver was crowded up, and there was dulness below the ninth rib; with the compression of the lung there was no bronchial respiration, but crackling râles. In such a case it is extremely difficult to say what the condition is.

There is another point of confusion: With the displaced liver we may have friction which can not be attributed to lung or liver exclusively. In other words, it is difficult to determine whether we are dealing with peritonitis or pleurisy. In many cases the pain may be due to a diaphragmatic pleuritis. Again, you may have a leucocytosis, but this does not help in the diagnosis, because it may be due to pneumonia or to appendicitis. Last winter, in the wards of our county hospital, a man was admitted with a diagnosis of appendicitis; on account of the urgency of the case I was asked to see him at once. Everything seemed to be fairly characteristic of appendicitis, and I did not wish to say positively that he did not have appendicitis. I did not recommend operation, and the next day he developed a pneumonia in the left lower lobe and everything subsided in the abdomen. I do not attempt to explain how this happened unless there was a combination of lower left pneumonia and appendicitis.

Dr. Thomas McCrae, Baltimore—Dr. Herrick has pointed out some pitfalls into which all of us may stumble. I have seen three such cases all admitted to the Johns Hopkins Hospital surgical wards. In a recent one there were marked abdominal symptoms which rather suggested an attack of appendicitis, but the patient had had his appendix removed. The appendix being gone, cholecystitis was suggested. Examination showed a very tender abdomen, the pain increasing with respiratory movements. Examination of the thorax revealed slight dulness at the right base. The next day there was tubular breathing. It is easy to be misled in these cases. The sudden onset of abdominal pain with fever, leucocytosis, and, above all, the marked local signs, all suggest an abdominal condition. Inspection may show diminished respiratory movement on one side, there is tenderness, etc. I agree with Dr. Herrick that a knowledge of the possibilities is our greatest safeguard, and with that a thorough and careful routine examination. The surgeons sometimes suggest that we delay too long before calling them in; but perhaps if they called in the physician oftener they would be saved the mortification of opening the abdomen in pneumonia.

Dr. James M. Anders, Philadelphia—It has been long currently stated that the pain is usually located in the vicinity of the nipple of the side affected, but this is shown by statistics to occur only in 50 per cent. of the cases; the pain is often referred to the base of the chest on the side affected. I have seen a number of instances in which the pain was referred to the abdomen. In two instances the symptoms closely simulated those of a cholecystitis, especially the local manifestations at the beginning. Later the pneumonic features dominated the scene. As Dr. McCrae has stated, the clinical picture very often simulates these abdominal conditions. I can also recall a case in which the pain was referred to the gall-bladder region and in which the patient died, came to autopsy, and a complicating cholecystitis was actually revealed. The diagnosis had been a right-sided pneumonia. During that patient's life the pneumonic symptoms, as is usual, dominated the clinical picture. I can recall another case, seen recently, in which pain was referred directly to the appendicular region. There was considerable rigidity of the right rectus, the abdomen was somewhat swollen, but there was no distinct tumor mass. A diagnosis of appendicitis had been made by two physicians, and it was thought the case ought to be referred to a surgeon for operation. A careful physical exploration of the chest was made, following the golden rule, "in all cases in which there is fever combined with abdominal pain make a careful physical examination of the thorax." A lobar consolidation was revealed. The abdominal symptoms finally disappeared. I believe we may regard the abdominal symptom as an exceptional occurrence after all in pneumonia. In the experience of some the pain seems to be more commonly referred to the lumbar region. It is to be remembered that cases of pneumonia in which the pain is referred to the lumbar region may occur in patients who previously have had a nephrolithiasis. A man aged 62 had nephrolithiasis on two occasions, and more recently a right-sided pneumonia; the pain was referred to the right lumbo-abdominal region. He had marked rigors and a history of a cough, which led to a careful examination of the lungs and the discovery of a right-sided consolidation. The patient insisted that he was suffering from another attack of renal colic on account of the location of the pain. It is most important practically, as Dr. Herrick has suggested, to investigate the thorax before rendering a diagnosis in cases presenting such symptoms as abdominal pains and fever.

Dr. James B. Herrick, Chicago—The diaphragmatic pleura is frequently involved when we have this pain referred to the abdomen; yet it is not necessarily involved. The case that Dr. Hall refers to, where there was a left lower lobe pneumonia, the pain being referred to the right side of the abdomen, is certainly confusing and is not clear of explanation. It is possible there was a slight pleurisy on the right side which was overlooked. It possibly may be attributed to an anastomosis between the terminal filaments of the intercostal nerves of the two sides. Gerhardt and Huss found, in making dissection, an occasional anastomosis between the intercostal nerves of the two sides and explained the pain on the opposite side from this fact. It is possible that some such explanation might explain Dr. Hall's case. Tenderness on pressure is certainly a confusing feature. Yet, in some cases that I have seen the tenderness has not been exactly that which is found in peritoneal inflammation. If we make gentle steady pressure with the flat of the hand rather than with the finger tips we shall often find that the pain is superficial and not of the kind that is found in peritonitis.

This whole subject is an old one and has been referred to by many writers on pneumonia, but it is frequently overlooked. I did not intend to take a crack at the surgeons, but as Dr. McCrae has opened up this line of thought I may say that in talking on this topic of referred abdominal pain with a couple of surgeons one said he had never heard of such a thing and the other said he did not believe it ever occurred. It was largely because of this conversation that I thought a paper on the subject might be timely and perhaps instructive.

THE PASSING OF CHRONIC RHEUMATISM.*

JAMES J. WALSH, M.D., PH.D.
Lecturer on General Medicine at the N. Y. Polyclinic School for Graduates in Medicine.
NEW YORK.

In response to the question, "Have you ever suffered from rheumatism?" addressed to the ordinary patient over 40 years of age, the physician seldom gets a negative answer. Even younger patients will tell of having had vague pains in their arms or shoulders, or in their knees or ankles, that they consider to have been rheumatic. Popularly, the notion is that rheumatism is one of the ills to which flesh is almost inevitably heir, and, in the course of time, practically every one is supposed to have some touches of it. It is not too much to say, then, that rheumatism is popularly considered to be practically a universal disease. Physicians encouraged this idea, to a certain extent at least, by suggesting that vague pains are rheumatic in origin, or at least agreeing with patients when they say that probably they have rheumatism.

As a matter of fact, many of the irregular practitioners in recent years, particularly the osteopaths, draw their clientele (and it is by no means innumerous), from the ranks of the so-called chronic rheumatics. Most of the proprietary medicines, besides their other wonder-working effects, are advertised to be good for chronic rheumatism, and especially for that fateful condition, the uric acid diathesis, which is supposed to be provocative of chronic aches and pains of many kinds.

To talk, then, of the passing of chronic rheumatism in the sense of the gradual disappearance of the affection during recent years, would seem to be highly paradoxical. Never, more than at the present time, did patients insist on treatment for the relief of pains and aches supposed to be due to chronic rheumatic conditions of one kind or another. That there are many symptom complexes to which the name rheumatism is commonly applied is beyond doubt. How many of these pathologic processes have anything in their underlying basis of causation to justify the name rheumatism is a very doubtful question.

Chronic rheumatism would supposedly be a condition in which some of the pathologic conditions of acute rheumatism persisted, and in which, as a consequence of this persistence, tissue changes of various kinds took place, causing a deterioration of joint structures. As a matter of fact, however, it will be found that while very many patients confess to chronic rheumatism, comparatively few will admit having suffered from the acutely painful red swollen joint, accompanied by fever causing confinement to bed, which characterizes true acute rheumatism. It is now generally conceded that acute articular rheumatism is a specific infectious disease, and while other specific infections, as, for instance, gonorrhea, influenza or typhoid fever, may produce disorganizing conditions in joints, it is a typical sign of acute rheumatic arthritis to go on to complete recovery. When changes in joints remain after acute rheumatism there is always some suspicion of the possibility of secondary infection, or even a doubt as to the original diagnosis, acute articular rheumatism having been the proper one.

A little examination of the cases commonly called chronic rheumatism shows how many disparate conditions are jumbled together under this term. Vague pains of any kind, for which no direct cause can easily be found, are at once called chronic rheumatism. Many of these conditions can be traced to definite nervous and mechanical conditions without much difficulty if careful examination of each individual case be made. I have already pointed out in previous papers that there are at least fourteen different achy conditions which are often called chronic rheumatism, but without any good reason. The most common form of pseudo-rheumatism is the relaxation of joints which occurs in the ankle and is known as flat-foot, or which follows the dislocations of joints producing tissue conditions which make the patients very sensitive for all their after-life to changes in the weather. Just as there are relaxations at the ankle joint, so there may be relaxations of other joints—the knee, the hip and the shoulder—which are apt to cause something of the muscular discomfort that becomes so prominent a symptom of flat-foot, or the use of dislocated joints in which relaxation has taken place.

A second very common form of vague pain usually attributed to rheumatism, occurs in connection with occupation neuroses. There is not a single occupation in which some movement involving the co-ordination of a number of muscles has to be made and frequently repeated, that may not be the source of pains and spasmodic inability to use muscles properly, such as occurs so commonly in connection with writer's cramp, or telegrapher's spasm. These movements need not necessarily be very complicated in order to have this discomfort develop. The lower limbs may be the subject of these occupation neuroses, as in the cases of men who work foot-power presses, or in those who run sewing machines, or even in nervous individuals who have to sweep much and constantly use the broom from one side supporting the weight on one leg, while the sweeping movement is accomplished with the arm. Filers, carpenters, launderesses who iron much, planers, men who have to use hammer and chisel, all suffer from these neurotic conditions, usually more painful on rainy days, and for this reason so commonly called rheumatism.

A third source of vague pains that may, if not carefully investigated, be attributed to rheumatism is neuritis. In persons who are exposed to the weather and who use one set of muscles much more than others, especially if at the same time there is the absorption into the system of such toxic substances as lead or alcohol, there not infrequently develops a neuritis of the nerve supplying the overworked group of muscles. Stonecutters, for instance, who use their deltoid and other shoulder girdle muscles for the purpose of frequently lifting a heavy hammer or mallet, and whose exposure to the elements leads them to take alcohol often in greater quantities than is good for them, develop a neuritis of that branch of the circumflex nerve which supplies these muscles. At first this makes the muscles much more easily tired than before. During this period other muscles in the neighborhood are asked to do more work than usual in order to make up for the paretic muscles. As a consequence, painful, overfatigued conditions develop. After a while, the neuritis continuing, there is

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

almost complete loss of power in the deltoid, and then the man can no longer pursue his occupation.

It must be remembered that the branch of the circumflex nerve which supplies the deltoid muscle at the shoulder also sends certain filaments to the joint structures of the shoulder. These filaments are really trophic fibers, and as a consequence the neuritis set up in them causes a lowering of the nutrition of the joint structures. This, together with the forced disuse owing to the inability to use and co-ordinate the muscles of the shoulder girdle, leads to something resembling degenerative changes within the joints. Points of tenderness develop especially over the head of the humerus, and the absence of synovial fluid may lead to crackling and roughness, so that there is some grating or fremitus when passive movements of the joints are made. It is easy to attribute such conditions to chronic rheumatism and to consider the neuritis in the case as rheumatic in origin and perhaps secondary to the joint changes, if the examiner does not follow out the history of the case carefully and examine what was the real beginning of the pathologic condition.

Some of these neuritic cases run a very insidious course, and it may not be clear for some time what the condition actually is. A very characteristic illustrative case of this kind has been recently under observation. The patient was a painter who did inside work, being occupied mainly with the painting of balustrades, doors, window-frames, and picture-moldings, requiring him frequently to occupy awkward positions and use many movements of the wrist in painting small carved portions of woodwork. He came complaining of vague pains in the forearm, and occasionally in the shoulder, which were worse on rainy days. He had been a painter for nearly ten years, and had never suffered from any symptoms of lead poisoning. There was no blue line on his gums. I concluded that it was a simple occupation neurosis, since the tired feelings that he described, and the tendency not to be able to work after a while, and the fact that the use of the brush in his left hand for a time had caused the development of the same condition, to a slight extent at least, in the other arm, were characteristic of such ailments.

One day he came to be treated for a sprained wrist. He had fallen on his right hand, and there was some effusion into the joints of the wrist. Two days later he appeared with a characteristic drop wrist. This had developed during the night, and his observation with regard to other painters rather led him to suspect what the true nature of the condition was. It is not unusual for drop wrist to develop after some injury to the part, just as it is quite a common story to have the first symptoms of toe drop as a result of alcoholic neuritis follow upon a sprain of the ankle. In both cases it is evident that for some time, probably for months, there has been a slow running, low grade and practically latent neuritis. It can easily be understood, however, how the preliminary manifestations of this would be a fatigue of muscles coming on much easier than before the nervous affection began, and a tendency to neurotic conditions such as occur in occupation neuroses because of the difficulty of co-ordinating complex muscle movements when the nerve paths leading to the group of muscles are disturbed by the presence of inflammatory products.

A certain number of cases of so-called chronic rheumatism here in America which present evidences of degeneration in joint structures following acute attacks of arthritis, are undoubtedly not genuinely rheumatic in origin, but are of gouty nature. Gout is much more frequent in this country than has been considered to be the case. Ordinarily gout is considered an English disease, and we look for English heredity in those in whom we suspect its presence. The absence of such heredity is, in many physicians' minds, an argument against an affection being gouty. Ordinarily, it would be considered, I suppose, not too much to say that gout is at least four or five times more frequent in England than it is in America. As a matter of fact, the comparison of the statistics of patients admitted to Johns Hopkins Hospital in Baltimore suffering from gout with those admitted to St. Bartholomew's Hospital in London for the same affection are in the proportion of only three to four. That is, gout is three-fourths as frequent in this country as it is in England. How difficult it is at times to differentiate acute gout from acute rheumatism may be judged from the confessions of excellent clinical observers, including Professor Osler himself, that only after two or three attacks of supposed acute rheumatism have occurred in a series of years in patients under their observation did they find the gouty nodules in the ears or the tophi in the fingers which proved that former attacks had been gout, and not rheumatism.

Gout is, in this country, earned rather than inherited. It occurs especially among those who are subject to the influence of lead and those who indulge too freely in malt liquors. While our beer is much less likely to cause the condition than the heavier malt liquors of England, there is now no doubt that the increased consumption of even light beer which has occurred in recent years in this country have made many more people liable to gouty attacks than before. As to lead poisoning, it must not be forgotten that besides painters and workers in lead factories, plumbers, typesetters, stereotypers and others engaged in the printing trades are likely to suffer from lead poisoning if they are susceptible to plumbum. The accumulation of lead in the tissues always predisposes to gout and leads eventually to changes in joints which may be described as chronic rheumatism if the real nature of the pathologic condition and its true etiology are not recognized by careful elicitation of the history of the case.

In recent years the condition known as rheumatic gout, or rheumatoid arthritis, or, better than any of these names, since it does not assume a knowledge of the etiology of the condition of which we have not yet described well, arthritis deformans, has occupied much more attention. We now know that this condition may occur in three forms. There is the slow running form, which begins usually as Heberden's nodes, and sometimes, though not always, goes on to involve other joints besides the terminal joints of the fingers, and so causes deforming, disabling deformity. The pathologic basis of this is a true productive osteitis of the ends of the bones near the joint surfaces, which seems to be due to the presence of irritants in the blood. It occurs by preference in nervous people. The acute attack of pain and discomfort in the affected joints, which are noted especially at the beginning of the affection, are likely to be more frequent and more annoying whenever the patient is under emotional stress or suffering from worry for any reason.

The second form of rheumatoid arthritis is usually called osteoarthritis and in contradistinction to the first it occurs more commonly in men than in women; it is seen by far most frequently in elderly male subjects. It

consists of a true osteoarthritis usually confined to the hip joint and spoken of by orthopedists not infrequently as senile coxitis. It may occur also in the joints of the spinal column, producing a certain amount of soldering together of the vertebræ and consequent fixation of the back, which gives a very characteristic gait. Like the affection of a single large joint, this spondylitis deformans may be absolutely confined, as its name indicates, to the vertebral column, and is, in fact, usually so confined. This form of the arthritis deformans may occur in younger subjects than the coxitis deformans already referred to.

Neither of the two forms of rheumatoid arthritis described are likely to be taken for rheumatism by a carefully observant practitioner, though very few patients suffering with these affections come under treatment without being convinced that they are suffering from an affection of rheumatic origin. The third form of rheumatoid arthritis, however, has many symptoms in common with rheumatism, and is undoubtedly one of the main reasons why acute rheumatism is thought to produce chronic pathologic conditions in joints oftener than it really does. This third form of arthritis deformans, called by English observers acute rheumatoid arthritis, is described very well by W. Hale White in the last number of Guy's Hospital Report, Vol, 57, 1902.

This third form of arthritis deformans occurs for the most part in women whose age is usually not far from 20. The disease begins, or is at any rate most prominent, in the proximal phalangeal joints, differing in this from the slow-running form of arthritis deformans which in elderly women begins in the distal phalangeal joints. Acute rheumatoid arthritis is usually strikingly seen in the wrists. It is markedly symmetrical, as a rule, in both hands. The swelling is considerable, and extends beyond the affected joints, so that there is a distinct fusiform swelling about the interphalangeal articulations and a general swelling about the wrist and other joints. Sometimes a creaking may be felt, due apparently to thickening of the synovial membranes. In the course of a very few weeks, as a rule, most of the joints in the body are affected, so that the patient becomes bedfast, and is unable to move fingers, thumbs or wrists, and sometimes not the elbows, shoulders nor even any of the joints of the lower extremities. The joints of the spine are often affected, so that turning in bed is difficult and painful, and the temporomaxillary joint is frequently implicated, so that mastication becomes a matter of great discomfort.

Muscular wasting is so very rapid that it is clearly an extreme degree of genuine arthritic atrophy not dependent on disuse. The wasting is usually seen best in the hand and forearm, but in a bad case all the muscles may become distinctly atrophic. The most interesting thing about the disease is the temperature. There is a daily rise toward evening up to 101 F. or 102 F. Exposed parts of the patient are likely to be covered with sweat, and, as can be readily understood, there is strong simulation of acute articular rheumatism. The points of differentiation from articular rheumatism are quite clear, however. The disease begins in the fingers, gradually affects all the other joints, seldom fails to involve the temporomaxillary joint, and very commonly affects the joints of the spine, which are seldom attacked by true acute rheumatism. The disease runs a definite course, the temperature coming to the normal after three to four weeks. Much immobility and some swelling around the joints remain. Most patients have a distinct tendency to relapses during which the joints are once more swollen and tender as before. After the febrile stage is passed swelling of the synovial membranes and the soft tissues around the joints remains and the muscular atrophy causes disability. This condition may not improve much, and the patient may remain a chronic invalid.

It is easy to understand how cases of this kind, which have been described by such excellent observers as Garrod and Bannatyne, as well as Hale White in England, would give the impression of an acute rheumatism running over into chronic rheumatism. This form of arthritis deformans is, however, a disease by itself, usually following some infectious fever, as influenza, parotitis, tonsillitis or the like, and perhaps itself of specific microbic origin.

It is easy to understand, from all that has been said, what little space is left for so-called chronic rheumatism. There would seem to be a few cases of true acute rheumatic arthritis, or of the subacute variety which produce changes in the joint tissues that are persistent and progressive. There is a growing impression that even of these few cases the majority are due not to rheumatism alone, but a mixed infection, the secondary infection being responsible for the persistent pathologic lesions. Certainly cases of true chronic rheumatism, that is of progressive pathologic changes in joint tissues for which no other cause except rheumatism can be found, are very rare. So much so, very probably, as to constitute them a medical curiosity. Personally, I should like very much to see such a case, for I am free to confess that I have not as yet seen one.

Is it possible, then, that chronic rheumatism is to be discussed without even a mention of the uric acid diathesis. Personally, I see no reason for hauling in a diathesis for which we have no substantial proof. Certainly the vague pains that are usually attributed to the uric acid diathesis or to lithemia are, in my experience, due more to a neurotic constitution as a predisposing factor and overwork of particular groups of muscles usually under unfavorable conditions as a direct etiologic agent, than to any other cause.

This, of course, does not deny the existence of any of these achy, painful conditions, which are so common and so frequently demanding treatment. It does not deny that during damp weather, and in people who work or live in damp locations, there will be a distinct tendency to chronic aches and pains, just as there would be to frequent toothache under the same circumstances. It only transfers these affections from the column of chronic rheumatism, where they are all jumbled together, to the manifest opprobrium of our therapeutics, to separate columns, with regard to some of which we know our therapeutic impotency, but with regard to most of which we are fully aware that massage, rest, local treatment and improvement of the constitutional condition will do much to get rid of the symptoms. If the general public and the majority of the medical profession were once persuaded that chronic rheumatism, instead of being a common ailment, is, indeed, very rare, then there would be less failures of diagnosis, with consequent inevitable failures in treatment and less resort to our osteopathic friends, the enemy, and to the many remedies that are supposed to alter the uric acid diathesis and get rid of chronic rheumatic tendencies.

DISCUSSION.

DR. JAMES TYSON, Philadelphia—Dr. Walsh has essayed a difficult subject, difficult as are all subjects characterized by an unknown or at least inexact pathology. There is confusion between gout and chronic or subacute rheumatism. While I

think it is true that gout is a more frequent occurrence in America than has been supposed, I do feel sure that a great many cases are called gout without sufficient reason. I do not think a diagnosis of gout is justified unless there is or has been podagra, or uratic deposits in the joints or evident hereditary tendency. Heberden's nodosities, regarded as gouty by so many, may be gouty, but more frequently perhaps are a product of rheumatoid arthritis. I wish to urge on my fellow practitioners of medicine an attempt at more precise diagnosis of the two conditions. I am sure that in certain cases in my own experience many years have been required to determine whether a case be one of gout or rheumatism.

I should like to say a word also on the threadbare but still undetermined subject of the uric acid diathesis. I sympathize with Dr. Walsh in this respect, and it is mortifying to note how often rheumatic pains are ascribed to the uric acid diathesis without any reason whatever. It is often a careless expression, and not always intended by those who use it, but it gives an impression to the laity which is erroneous. As Dr. Walsh says, we really do not know what the uric acid diathesis is. There is, however, a clinical complex consisting in a scanty secretion of urine, of high specific gravity, with constant and copious deposits of uric acid and urates which is associated with the uric acid diathesis and is evidence of its presence. But it must be a permanent condition. It has doubtless happened to many of us to note in the morning after a liberal dinner including wines a scanty urine with uric acid deposits, etc., which will wear away after liberal ingestion of water, but this temporary state is not the uric acid diathesis. In the conditions referred to even the ingestion of large quantities of water does not increase the amount of urine secreted, and the tendency to sediments continues. To this condition I think we are justified in applying the name "uric acid diathesis." Such cases are not very numerous, and it may happen that associated muscular and joint pains are the result of it, but one ought at least to be sure of the combination before one asserts the causal relation.

Dr. Thomas McCrae, Baltimore—Dr. Walsh has faced a question that the majority of us have faced frequently, and often with the diagnosis of "chronic rheumatism." The profession is largely to blame for the ideas the public have regarding this condition; we inherited the idea and pass it on. Dr. Walsh brought out a good point when he said that if one made a diagnosis of acute articular rheumatism and, after the attack is over, joint changes persist, then consider a wrong diagnosis; if we did that we would find fewer mistakes.

Dr. Alexander Lambert, New York—This helter-skelter diagnosis of rheumatism has been made for a long time, and my confrères in New York should take a more self-respecting attitude toward these painful affections. Often the diagnosis is easily made. It has for a long time struck me that so-called cases of chronic rheumatism with active tissue changes, ulnar deformities, etc., have nothing to do with rheumatism. It is perfectly true, in my opinion, that many cases began like articular rheumatism which can not be differentiated from it, which later prove to be true cases of arthritis deformans. In my experience this is seen most commonly in young women.

Gout is much more common in New York of late years, and it is certainly more often met with in hospital work than formerly. A great many cases that at first seem to be cases of rheumatism and yet which are treated as gout get well, and this is especially so in women where you get so often this irregular type of gout. That type of real chronic rheumatism is, as Dr. Walsh has stated, one that we must disregard. There are cases of rheumatism which begin as acute articular rheumatism, and before the patient recovers from one attack entirely they may have another acute attack and then run on into a subacute condition that one must look on as chronic, a chronic articular rheumatism. This process runs along a long while and leaves the patients more or less crippled. A great number of mistakes come from calling real gout rheumatism, and the ideas that are so prevalent regarding the uric acid diathesis have much to do with it. I am only too glad to be able to add my protest against this asylum for lazy diagnoses. I think it is firmly believed that the uric acid diathesis, occurring in healthy, vigorous, athletic, strong young men, is the cause of nearly all the woes they are heir to, especially the muscular pains. Whatever causes gout causes uric acid, and uric acid is simply one of the many symptoms. These men were usually 20 years old, and no one would accuse them of being gouty or rheumatic; they were in their prime and in vigorous health, and yet, among such, uric acid deposits in the urine are frequently found.

I wish to thank Dr. Walsh for bringing this subject up, because it is only by such papers and by such discussions can we realize that the so-called cases of gonorrheal rheumatism, scarlatinal rheumatism, etc., are not cases of rheumatism at all, but distinct and definite diseases; all cases having pains in the joints should not be always considered as rheumatic, but they should be clearly differentiated. It is only by so doing that we will be able to be honest with ourselves and arrive at an accurate and scientific knowledge of the subject.

Dr. James J. Walsh, New York—When I called my paper "The Passing of Chronic Rheumatism" I did not mean absolutely no cases of chronic rheumatism existed; I did mean to say that cases of chronic rheumatism were more or less curiosities and well worth studying. Chronic rheumatism is generally thought to be very common. If one should run across a case of true chronic rheumatism we would want a report of it in our journals. What is acute rheumatism? We think it is an acute infectious disease. A number of clinicians think the disease runs a course of from two to six weeks and gets better; they give salicylates, not because it is a specific for rheumatism, but because it lessens the pain and lowers the temperature. Again we have certain joint lesions occurring in gonorrhea, scarlet fever, typhoid fever and intestinal troubles that are accompanied by diarrheas, dysentery, etc., all of which may be accompanied by joint lesions and to which the term "rheumatism" is applied. I wish to enter a plea for a better knowledge of this condition.

It gives me pleasure to hear what Dr. Tyson has said regarding the uric acid diathesis; I think the uric acid diathesis has been overdone when we say that it gives rise to so many aches and pains, etc. If one looks into the literature one will find little authority for thinking the uric acid diathesis a prominent factor in disturbances of metabolism. We must remember that nervous people are more subject to pain than others; they may simply have some discomfort and think they really have pain, and such is particularly worse on rainy days. Dampness is associated with it.

DANGERS ATTENDANT ON ATTEMPTS AT GAINING THE INTERVAL IN OPERATIONS FOR APPENDICITIS.*

RICHARD H. GIBBONS, M.D.
SCRANTON.

It is strange that medical men in general and anatomists and physiologists in particular claim that the appendix vermiformis has no function, that it is a useless appendage, playing the part of catching any old thing, or furnishing the surgeon opportunity to rake in ill-gotten gain. Ridiculous as it is to compare inanimate things to parts of the human body, it may be well to do so here, in order to state that at such a right-angled junction as is formed by the ileocecal connection, an oil cup would be furnished in mechanics, while in hydraulics, as in a sewerage system, for instance, a manhole would be placed. This appendage apparently has secretory functions by which, it is fair to assume, the natural tendency to pastiness of the residue of digestion, after it comes to the cecum, is so modified that it is ren-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

dered less adhesive; the cecum being the receptacle for the effete fecal mass needs, it would appear, lubricating material, and this assumption indicates the necessity therefor, in order that the fecal current and the propulsion of the mass may not become interrupted. Whether this assumption is based on incorrect reasoning, the physiologic chemist ought to be able to demonstrate.

A normally situated appendix free from disease means to its possessor, other things being equally normal, that he shall be freer than others from the one great danger attendant on life from the cradle to the grave—constipation. Understand that no inference is to be deduced from this statement that constipation is the cause of appendicitis; on the contrary, appendicitis or appendiceal irritation, from which one may suffer a great part of his lifetime before sufficiently extensive involvement takes place to make up the condition known as the "attack," is always productive of constipation; mark the distinction as well as the difference. Constipation seldom, if ever, produces appendicitis. Diarrhea may occasionally do so; these conditions usually are but symptoms of the disease; that they are relieved by non-surgical means is not evidence that they were the cause of, nor that it is cured by such relief.

This brings us to the consideration of the many ailments referred to the gastrointestinal tract during infancy and childhood which are often misinterpreted as "gastric difficulties," "cholera infantum," "cholera morbus," "colic," "gastrointestinal," "intestinal" and "nervous dyspepsia," "liver ailments," "constipation," or even "diarrhea"—for a diseased appendix quite as often causes diarrhea as constipation, and sometimes we note these conditions alternating in given cases. Such "ailments," "difficulties" and "disturbances" are nearly if not always, due to a diseased appendix, the disease condition, located in its mucous membrane, having been produced by some infection, the result of impure food-product, or by the exanthemata, influenza; or, catarrhal inflammation due to cold is as likely to affect the mucous membrane of the appendix as mucous membranes elsewhere, even to the extent of slight superficial ulceration thereof, each attack passing through the various stages on to the process of cicatrization, the appendix itself not showing any marked pathologic change at the time of these repeated ulcerative attacks. Eventually the stenosed or strictured conditions following the inflammatory changes show up as cicatricial contractions and these form more or less perfectly retentive diaphragms which interfere accordingly with the complete emptying of the appendix of its secretions, or its attempts at ridding itself of foreign particles that may be accidentally forced into its lumen; an appendix thus crippled during infancy or childhood, while a menace to perfect health and likewise to life, may not until years after the initial disturbance cause highly dangerous or fatal effects. During these years the symptoms may be of the character known as "digestive disturbances," and the patient may have taken numerous forms of quack nostrums.

In making our diagnoses for appendicitis we should have to contend with but three forms of the disease: the pre-inflammatory, the inflammatory, and the post-inflammatory. Further division and subdivision serve but to confuse and bring about an obscure or doubtful diagnosis which in turn serves to bring about delay until the opportune moment is passed. In our examinations let us not look for symptoms alone at the great risk of misinterpreting them; rather let us look for signs, one sign in particular, that of tenderness.

This sign was pointed out to us years ago by Dr. Charles McBurney of New York City, and it is almost infallible in determining the condition of advancing inflammation of the appendix. As you know, its presence is made manifest by pressure being applied at the point that is known to be the normal site of the base of the appendix when it is involved by lymphangitis. McBurney described it as a point of exquisite tenderness, and his friend, Dr. Lewis A. Stimson, also of New York, named it "McBurney's point." A number of years ago I evolved a process of reasoning from my then somewhat limited knowledge of this subject and accordingly wrote an article which was published in the *New York Medical Journal,* April 18, 1891, page 452. At that time I entertained ideas that somewhat deprecated the value of this sign. Greater experience, however, has taught me to regard it most highly. I felt somewhat diffident of having published this article until about a year ago, when I read the statements regarding this point from the pen of the distinguished surgeon, Sir Frederick Treves. In his article he attempts, without success, to belittle the McBurney point as a sign of appendicitis by stating that he found that the location of the appendix in his postmortem work did not correspond with the "point" as noted in the living subject.

The refinement of the diagnostic sign of McBurney, palpation of the appendix, as given to us by Dr. Geo. M. Edebohls of New York, is the open sesame to the dismal cavern of appendicitis, for by this key, that of palpation of the appendix itself, we can trace its entire outline, and also detect the tenderness caused by disease situated within its walls and this during the pre-inflammatory stage. Hence its exceeding great importance, for on recognition of the relative value of these tests of McBurney and Edebohls and their application and prompt action as a result of the knowledge gained thereby, will depend the relative danger of early as compared with late operation.

The symptoms of acute appendicitis are of so definite a character that "he who runs may read" and the physician listening to the history of one suffering from an "attack" ought to be able to make a diagnosis by telephone and that even at long distance. Had one in his enthusiasm during the discussion of this subject at our last meeting made an appeal for a certain great leader of fashion, then the uncrowned King, to set a pace for the world to follow by having his diseased appendix removed, such disease condition having been interpreted from the daily press reports of his "stomach troubles," "intestinal difficulties," "influenza," and last, but by no means least, "lumbago attacks," how such a one would have been laughed at; and yet any experienced American physician or surgeon would have been warranted in interpreting these reports of the case, even at that time as meaning nothing else but appendicitis, thus making a diagnosis even by cable. The primary danger in connection with appendicitis is that the pre-inflammatory stage of the disease is not detected; this being due to the old time nonsensical ideas, among which that of a tumor of perityphlitic origin is uppermost, having been too strongly entrenched in the minds of many medical men. What a multitude of woes, miseries and sufferings could be swept away were we but to recognize in the infant or child its mildly diseased appendix, which in time, if left to the uncertainty of medical treatment, plus dietary juggling, must come to the inevitable state of diffuse inflammation, when still greater danger be-

comes attached to the situation, and this even though we operate at the very earliest hour of this stage of "attack." If we operate late in the attack, let us not forget that the operation may be followed by hernia, "to plague the patient and vex the surgeon," as Joseph D. Bryant has so aptly said.

The greatest danger of all, however, in connection with the diseased appendix is that of the "wait and watch" method of treatment, consisting of no matter what kind one may suggest, from the most heroic to that of the complete "let alone plan," instead of surgical intervention, until hour after hour has flitted away in the vain and forlorn hope that lost opportunity may return, until we find ourselves facing a problem, the outcome of which is most dubious regardless how well calculated may be its attempted solution. No amount of medical treatment or dietary adjustment can ever make amends for the delay that leads us into such a predicament. Every hour so lost regardless of what one's fancy may choose for him in his attempt at regaining this lost opportunity, the more surely adds its own danger, until danger after danger beset the path chosen so recklessly, as he casts aside the opportune moment for surgical treatment of which, if he take advantage, he will be saved embarrassment, to say the least. Another and very grave danger attendant on attempt at gaining what may seem to be the golden opportunity for surgical interference, or operation during "interim," is that the patient finding that he has recovered from his "attack" believes, and is encouraged by his medical attendant in thus believing, that he may have been "cured," so he flatly refuses to have an operation at this time, favorable and all, though it may seem to him. A number of such cases must have come under the observation of every medical man of considerable experience with patients afflicted with the disease. I have had quite a number; many of them are still miserable; some have died from other attacks, no operation having been performed, while a few have not been re-attacked; their time is yet to come. So that, after all due consideration has been given to the dangers attendant on attempt at gaining the "interim" in the operation for appendicitis, it would seem apropos to here cry "physics to the dogs," and that *immediate* surgical intervention should be the shibboleth of every physician and surgeon! To play on the immortal bard's great creation, the Soliloquy of Hamlet, why should not the sufferer from a diseased appendix say: "Doctor, why not rather *bare* the ills I now have than wait for others that you know not of?"

Treves says what is so well known even here in America, that there will die but about five per cent. of those first attacked by appendicitis! What man among us would be satisfied with a loss by death of five, two, one, or even a still smaller percentage? He also makes the statement that out of one thousand operations for appendicitis, during "interim," he has had but two deaths; so far, so good. The mortality need not be as great as one-hundredth of 1 per cent. if immediate operative measures be resorted to, on recognition of the disease during the pre-inflammatory stage. Why should Treves have had a death at all under such favorable conditions as surrounded his thousand cases? But has he told us how many people died during the process of treatment under which they must have gone, and that at the hands of many doctors, most likely, in order that each one of this apparently great number should get to the goal of his, Treves', ambition—the day of "interim"? If there were not accompanying deaths attendant on this doctoring, great was the feat, and we should know of what it consisted. Will any one here, even our friends Ochsner and Mayo, make any such heroic attempts as trying to get together one thousand cases for interval operation in appendicitis, without death attending at least 2 or 3 or even 5 per cent. of the number, and this even during the "first attack"? Ochsner should make himself more clearly understood here in New Orleans than he appears to have done elsewhere. A short time ago I listened to a report of the meeting held in Saratoga. The reporter took great umbrage when, in discussing his so-called "impressions" of the meeting, I made the statement that Ochsner did not pretend to more than attempt to get his patients in better condition for operation, which he performed as soon as it became satisfactory to him. The gentleman and others, his friends, took issue with me, all claiming that Ochsner "cured," note the word "cured," those cases by treatment, operations not being resorted to but occasionally; in fact, they stated that all of the successful cases reported in his discussion of Deaver's, La Place's and Parker Syms' papers at the Section's last meeting were not operated on at all, but were "cured" by his (?), Ochsner's, method of treatment.

In conclusion permit me to say, Mr. Chairman, that here in the South, and elsewhere, New York, Boston and vicinities, physicians in general are progressive and quite up to date in the management of appendicitis, while it is sad to note that in Pennsylvania, even though it be my own state, physicians, not always of the highest standing, however, point the finger of scorn and rail at passing brothers who stick to the surgical maxim, "Operate, and operate early!" So when Deaver says he has different cases from those seen in Chicago it is the truth, for perhaps in no other place on earth can the sodden, painful, phlegmonous mass typified so graphically in Joseph Price's "Green Groin" be as plentifully seen as in the City of Brotherly Love, and this in spite of Deaver's teaching, the following of which would but revert directly to the contrary of all of this.

DISCUSSION.

Dr. H. D. Niles, Salt Lake City—So long as the large mortality from appendicitis comes from waiting for an opportune time to operate, so long as the small mortality comes from operating when we have the infection within the abdomen, so soon as the diagnosis is made, just so long, it seems to me, that we should operate immediately when we make the diagnosis. If we wait, we are waiting for the development of conditions that no man will now claim he can recognize. I do not mean by that that you can not tell the pulse or the temperature, or that you can not mention other symptoms, but no one can tell how dangerous it may be not to operate or how dangerous it may be to operate. No matter how small within the peritoneal wall, there may be that spurious and dangerous infection from the peritoneal cavity. With these uncertainties and with the expectation of occasionally choosing the wrong time, to me it seems best to operate when I know I have the infection, because I am not certain how long I can safely leave it.

Dr. James B. Bullitt, Louisville—One word in regard to the conception of the author's paper. My impression was that the question was whether or not Dr. Ochsner cures his cases with operation or without operation, and, therefore, I yield the floor to Dr. Ochsner.

Dr. A. J. Ochsner, Chicago—Evidently I have had the misfortune of being misunderstood. Since the Saratoga meeting of this Association I have stated my ideas on this particular point with the greatest possible care in the form of conclusions, which have appeared in the *Medical News* so that anyone who may be interested will have an opportunity in the future to see exactly what my position is regarding this subject. The

same thing has been done in a number of publications, but I have in this one considered every point that has come out in any and all of these discussions. These conclusions were formulated as follows:

1. The mortality in appendicitis results from the extension of infection from the appendix to the peritoneum or from metastatic infection from the same source.

2. This extension can be prevented by removing the appendix while the infectious material is still confined to this organ.

3. The distribution or extension of the infection is accomplished by the peristaltic action of the small intestines.

4. It is also accomplished by operation after the infectious material has extended beyond the appendix and before it has become circumscribed.

5. Peristalsis of the small intestine can be inhibited by prohibiting the use of every form of nourishment and cathartics by mouth and by employing gastric lavage in order to remove any substances of food or mucus from the stomach.

6. The patient can safely be nourished during the necessary period of time by means of nutrient enemata. Large enemata should never be given, for they may cause the rupture of an abscess into the peritoneal cavity.

7. In case neither food nor cathartics are given from the beginning of the attack of acute appendicitis and gastric lavage is employed, the mortality is reduced to an extremely low percentage.

8. In cases which have received some form of food and cathartics during the early portion of the attack and are consequently suffering from a beginning diffuse peritonitis when they come under treatment, the mortality will still be less than 4 per cent., if peristalsis is inhibited by the use of gastric lavage and the absolute prohibition of all forms of nourishment and cathartics by mouth.

9. In this manner very dangerous cases of acute appendicitis may be changed into relatively harmless cases of chronic appendicitis.

10. In my personal experience no case of acute appendicitis has died in which absolutely no food of any kind and no cathartics were given by mouth from the beginning of the attack.

11. The mortality following operations for chronic appendicitis is exceedingly low.

12. Were peristalsis inhibited in every case of acute appendicitis by the methods described above, absolute prohibition of food and cathartics by mouth and use of gastric lavage, appendectomy during any portion of the attack could be accomplished with much greater ease to the operator and correspondingly greater safety to the patient.

I would make the following suggestions for the treatment of appendicitis with a view of reducing the mortality:

1. Patients suffering from chronic recurrent appendicitis should be operated on during the interval.

2. Patients suffering from acute appendicitis should be operated on as soon as the diagnosis is made, provided they come under treatment while the infectious material is still confined to the appendix, if a competent surgeon is available.

3. Aside from insuring a low mortality this will prevent all serious complications.

4. In all cases of acute appendicitis without regard to the treatment contemplated the administration of food and cathartics by mouth should be absolutely prohibited and large enemata should never be given.

5. In case of nausea or vomiting or gaseous distention of the abdomen, gastric lavage should be employed.

6. In cases coming under treatment after the infection has extended beyond the tissues of the appendix, especially in the presence of beginning diffuse peritonitis, conclusions four and five should always be employed until the patient's condition makes operative interference safe.

7. In case no operation is performed neither nourishment nor cathartics should be given by mouth until the patient has been free from pain and otherwise normal for at least four ys.

8. During the beginning of this treatment not even water should be given by mouth, the thirst being quenched by rinsing the mouth with cold water and by the use of small enemata. Later small sips of very hot water frequently repeated may be given and still later small sips of cold water. There is danger in giving water too freely, and there is great danger in the use of large enemata.

9. All practitioners of medicine and surgery, as well as the general public, should be impressed with the importance of prohibiting the use of cathartics and food by mouth, as well as the use of large enemata, in cases suffering from acute appendicitis.

10. It should be constantly borne in mind that even the slightest amount of liquid food of any kind given by mouth may give rise to dangerous peristalsis.

11. The most convenient form of rectal feeding consists in the use of one ounce of one of the various concentrated liquid predigested foods in the market, dissolved in three ounces of warm normal salt solution introduced slowly through a soft catheter, inserted into the rectum a distance of two to three inches.

12. This form of treatment can not supplant the operative treatment of acute appendicitis, but it can and should be used to reduce the mortality by changing the class of cases in which the mortality is greatest into another class in which the mortality is very small after operation.

In regard to the first point, I wish to say here, as I have said everywhere before, so long as the infection is within the appendix when I make the diagnosis, I operate immediately if I can obtain the consent of the patient. I have stated the reasons why this should be done over and over again.

There is, however, a time that has been described by Dr. Niles, a time which comes to every surgeon, when we can not say with any degree of certainty that the particular patient under consideration will get well if we operate at once. This class of patients, under the best possible conditions, and with the best possible surgeons, will produce a mortality of from 15 to 30 per cent. if they are operated on at once as soon as the diagnosis has been made. I wish to say that with those cases we do not know what will happen if we operate at once. We do know, however, that in 97 per cent. of all such cases suffering from perforative or gangrenous appendicitis the patient will get well, provided we follow out the plan outlined in the above conclusions, namely, that of washing out the stomach, and giving absolutely no cathartics and no food of any kind by mouth and giving no large enemata until the patient has been normal for at least four days. We have counted the leucocytes and have found in all cases in which this treatment was carried out that the abnormal leucocytosis has decreased. We have found that the pain and the tympanitis disappeared regularly and that the patient's condition has improved systematically, and that although there is still a slight mortality, this has been diminished enormously by this form of treatment, not only in my own hands, but also in the hands of a large number of physicians and surgeons who have carefully carried out all of the details of this plan of treatment. Those who have failed have either permitted the use of a little food by mouth or they have neglected to employ gastric lavage or they have given large enemata.

DR. MILES F. PORTER, Fort Wayne, Ind.—We have operated in the beginning of the attack on several hundred cases and we have not lost a single case. We have counted these cases just as they come into the hospital; not only the cases in an operable condition, but those which died right after they entered the hospital. Some cases should be operated on after they recover from that attack, at a safe period of time. Occasionally we have a death, but we have only had 2 deaths this year out of 130 cases. Neither of these cases should have died, but the one died from pneumonia and the other from shock.

DR. WILLIAM J. MAYO, Rochester, Minn.—I think we are all agreed on one point—the point on which Drs. Murphy, Deaver and Ochsner, and so far as I know almost every prominent surgeon in this country has insisted—that if you can get the case within the first forty-eight hours that case

should be operated on, and the sooner you operate the safer the operation will be. The more experience I have the more convinced I am that this is the proper course to pursue. Now, if you have a case that comes to you in which you believe that the inflammation is still confined within the appendix and the patient is still in a reasonably good condition, I do not care whether it is during the first forty-eight hours, or whether it is during the third, fourth or fifth day, I will operate on that case, because I believe that that case is going to get well. We have, at least out in Minnesota, a considerable number of cases brought to the hospital in which this favorable condition has gone by. The patient is tympanitic, vomiting, with quickened pulse, and we realize that no longer by removing the appendix can you get the material out of the system, and if you operate on this case at this time there will be a very considerable mortality. If you take these cases that show this septic condition (and Dr. Lund has shown us how to take care of some of the worst of them) and put them on the plan of treatment recommended by Dr. Oschner, in a few days the majority will get into a condition in which they can safely be operated on with a mortality of 4 per cent. or less; at least this has been our experience.

Dr. J. B. Murphy, Chicago—I feel that I have for the past two years understood Dr. Ochsner's position as he has stated it here to-day. I feel that the majority of practitioners have not properly interpreted his position, and that Dr. Ochsner has been greatly wronged and injured and maligned by many practitioners. I am delighted to find that we are practically a unit as to what should be done in cases of appendicitis. I do not see wherein we differ at all. There are cases, however, which we can not rescue by operation at the time they are brought into the hospital, which we can reach by operation at a later time. These cases are so small in number, however, in comparison with the whole, and the number will become smaller every day so soon as we understand that the profession is a unit, including Dr. Ochsner, that the cases are all better operated on within the first twenty-four or forty-eight hours, and that we ought to make a diagnosis before that time, and a practitioner will be ashamed to come in with a case after that time has elapsed. He can no longer say, "I have given this patient the 'Ochsner treatment,'" when the patient is presented in a moribund condition.

Dr. R. H. Gibbons, Scranton, Pa.—A bright, pretty girl, 16 years of age, a miner's daughter, was "attacked" during the evening of a Thursday of June last. A physician was called and prescribed for her, stating that she had a "bilious attack." On the following Tuesday I visited her in consultation, finding her abdomen enormously distended. It was recommended that she be taken into hospital that attempt might be made to get her in a more favorable condition for operation. I explained to her family the danger attendant on shifting her over the rough roads in one of the crude ambulances with which we are usually furnished throughout the coal regions, so she was not changed. I tried to have her physician appreciate the importance of keeping from her all forms of drugs, and even food or fluids, and to nourish her, if necessary, per rectum. This was an unsuccessful undertaking. At the end of two weeks, when I was again called. I found her condition was worse, if possible, than on the former occasion. I persuaded her family to have her removed at all hazard to a private hospital several miles distant; this was successfully accomplished. A rigid nursing surveillance was established, nothing was given by mouth, rectal alimentation was instituted. As is often noted to be so, when such patients are treated in this way the distension subsided, the peri-inflammatory exudate largely disappeared and the case assumed an altogether more favorable outlook, of which, when at its height, I proposed taking advantage, intending to operate. The already referred to danger attendant on attempt at gaining the interval opportunity now asserted itself. It was in this way: If the patient has done so well thus far why should she not make an entire recovery; in other words, why operate? These were questions that were put, not only by the little girl herself, but by various members of her family and others interested. While she was in this fairly favorable condition Dr. Robert F. Weir of New York City, while here in Scranton in consultation in another important surgical case, saw her with me, and said, as he had said at the meeting of a year ago, "that it was dangerous to postpone operation in any case." I regret exceedingly that I did not insist on operation at this time, for soon thereafter she was taken with symptoms which manifested themselves as those of pyophlebitis, and nothing whatever had the slightest effect on her condition, she finally dying on the forty-first day of her "attack." Dr. John A. Wyeth, who was in town spending a number of days in expectation of possible operation in a critical case of typhoid, also examined this case, but at a time when she was within a few days of her demise, when every organ in her body appeared to be under the influence of the general toxemia.

Special Article.

THE FOURTH OF JULY, 1903, CASUALTY LIST.

A. THE TETANUS MORTALITY.

Before the Fourth of July celebration began, accompanying the desultory explosions that precede it by several weeks, the daily papers throughout the entire country north of Dixie were full of warnings of what was to be expected. The experience of previous years was retold; how many lives had been lost through the accidents of the Fourth, and how many more had succumbed to the tetanus epidemic that follows in its train. There were countless warnings to parents, both of the dangers in the use of toy pistols and the necessity of proper care of the wounds they might produce. Much advice was given in this last respect that was for the most part good. The responsibility of municipal authorities was pointed out. Attention was called to innumerable ordinances controlling the sale of toy pistols to minors and the discharging of firearms in the limits of the municipality. Assertions were made that if existing laws were properly enforced by the police the events of preceding years could be much modified, if not eliminated.

But all to what avail? Already in Pennsylvania a foretaste of the coming calamity had been furnished by a preliminary outbreak of tetanus following a blank cartridge demonstration on Decoration Day. According to the newspaper accounts, more than a score of deaths had resulted from this cause alone, and the papers of Pennsylvania urged vigorous action on the authorities, and warned the people of the dangers the Fourth would bring. And yet Pennsylvania had the worst epidemic of tetanus after the Fourth of any state in the Union. The part played by the lay press in this particular feature of preventive medicine has been noteworthy, and entitled to the highest commendation. That it seems to have been fruitless is none the less credit, for we can not tell what the result might have been otherwise, and we know of much good that has been done through this warning of the press.

Now that the Fourth has passed, we are counting up its cost. With as general warning as could be given, the tetanus epidemic has come with even worse and more widespread violence than usual. Over four hundred families are mourning the agonizing death of some member, while a few, a very few, anemic, emaciated survivors are convalescing from one of the most terrible experiences that disease can bring. The impossibility

of educating the public, and more particularly its officers, to a state of action is too evident. There is no difficulty in educating the public to a point of horror and indignation that such things should be—but the steps necessary to terminate the wrong are not forthcoming.

Nor has the public alone been warned in vain. Hardly a medical journal in the country failed to speak of the same topic at the approach of the Fourth, and to urge the necessity of thorough surgical treatment of blank cartridge wounds, as well as the desirability of prophylactic use of antitoxin. Yet we now hear the same story of the boy who was taken to the family physician or the dispensary soon after being injured. "The doctor dressed the wound," or "tried to pick out the wad," or "washed it with antiseptics," or "thought it but a trivial injury, and said that it would be all right in a few days." And then comes the sequel that "after lockjaw had set in the wound was opened and it was found that pieces of the wad had remained at the bottom of the wound. These were removed, the wound was cauterized, and antitoxin was given. The boy died in great agony the next morning."

There has been an impression that this year's epidemic has been more severe than usual. However, there has been nothing reliable with which to make comparisons, and the impression has been gained chiefly through newspaper reports. Some of the daily papers, notably the *Chicago Tribune,* have made praiseworthy efforts to keep track of the number of deaths reported to them by the press bureaus and otherwise, but such information is obviously incomplete. There also exist various impressions as to the modes of infection with the tetanus bacilli, the sources of the organism and the nature of the wounds that most frequently introduce them. In order to place this subject on a basis permitting its study from the standpoint of preventive medicine THE JOURNAL has attempted to collect all the information possible concerning this year's outbreak. The total number of cases collected far exceeds the number collected by the various daily papers, because we have been able to secure reports from many small communities that never were put on the press wires. Obviously it has been impossible to verify all the reports we have received, and in order that any errors of omission or commission may be corrected we herewith publish a full list of the names of the victims, arranged according to states. Any additions or corrections that may be made by our readers, which may enable revision of these statistics and render them more valuable for future comparison, will be appreciated. While it is possible that in this list there are a few duplications, and a few cases reported as tetanus that were sepsis, or something else, on the other hand, there were undoubtedly many more cases that were not reported, and many cases have been omitted from the tables because the reports were questionable or unsatisfactory, so that the total, great as it is, is undoubtedly below the actual number of cases of tetanus that followed injuries incurred in Fourth of July celebrations. For purposes of comparison, to be made later, a number of deaths from tetanus caused by other than Fourth of July injuries have been included, but they have not been given numbers in the series:

In this table have been inserted such data as were obtained from the case reports. Those that were not given, or on which there were conflicting statements, have been omitted. The cause of injury is stated as it was reported, but whether the cause is given as toy pistol, pistol, or blank cartridge, it indicates in each case a wound produced by a blank cartridge. Under the heading of duration the figures indicate approximately the number of days elapsing between the receipt of the wound and the death of the patient, for the information obtained often did not give distinctly the number of days of incubation elapsing before the onset of symptoms. In the columns of results, × indicates a fatal outcome.

Distribution.—It will be noted that the Southern states are quite free from deaths of this sort, due to the fact that the blank cartridge celebration of Independence Day is not the custom in the South. A few such

cases follow the Christmas celebration, but as the noise of this celebration is mostly obtained through other means, tetanus is not common. In the Northern states the number varies somewhat according to the population of the states, but by no means strictly so, as will be seen from this table:

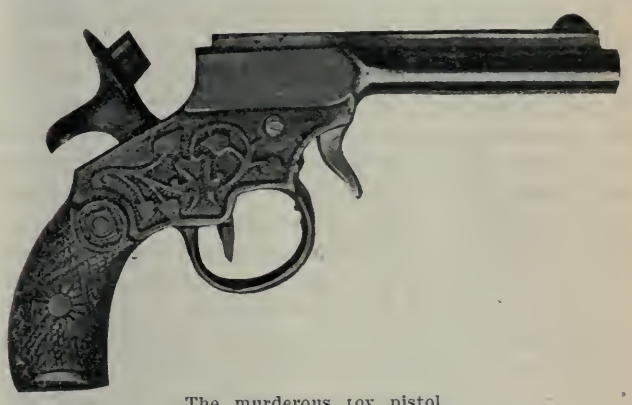

TABLE 2.

Pennsylvania	82	Connecticut	3
Ohio	67	Rhode Island	3
Illinois	49	Vermont	3
New York	36	West Virginia	3
Missouri	29	California	2
Michigan	29	New Hampshire	2
Massachusetts	16	Maine	2
Minnesota	15	Montana	2
Iowa	14	Oregon	2
Indiana	11	Washington	2
Kansas	11	District of Columbia	1
Wisconsin	10	Maryland	1
New Jersey	8	Indian Territory	1
Colorado	4	Idaho	1
Kentucky	4		
Nebraska	4	Total	415

New York had less than half as many deaths as Pennsylvania, and but little more than half as many as Ohio. Massachusetts also is below the number that might be expected from its population. Ohio shares with Pennsylvania a greatly excessive death rate. Otherwise the number of cases bears a fair relation to the population of the states. There are but a few Northern states from which there have been no deaths reported, namely, Wyoming, Utah, North and South Dakota, and Nevada, the small population of each of these states probably explaining the escape. The great number of cases in Pennsylvania and Ohio amounts almost to an epidemic, and no satisfactory explanation seems to have been given.

Age.—The age of the victims is, of course, low, for, with but few exceptions, they were small boys playing with toy pistols. There were a few girls, indicated in the table by the use of the full name, who attempted to emulate the boys, and suffered the penalty. A few adults also were included; they received their wounds in various ways, some, like the boys, through trying to use blank cartridges, some from other sorts of explosions.

Nature of the Wound.—The overwhelming frequency of the blank cartridge wound as the source of tetanus is evident from the tables. Of the cases in which information on this point was obtained there were 358 blank cartridge or toy pistol wounds, and but 29 said to be from other causes. In not a few instances, furthermore, in which the original report gave the cause as firecracker or some cause other than blank cartridge, subsequent information showed that after all the blank cartridge was the real offender, so it is possible that the proportion of cases produced by blank cartridges is even greater than these figures indicate. Reports of injuries by toy pistols have been accepted as indicating wounds produced by blank cartridges, for the reason that all the toy pistol injuries that have been followed up have turned out to be due to blank cartridges. The term "toy pistol" has an indefinite meaning, for it includes both the little affairs used for exploding flat paper caps as well as pistols manufactured for the use of 22-caliber cartridges. As a result many people have come to believe that the paper cap pistol is the offending weapon, which is incorrect. So far as it has been possible to learn, this sort of explosive does not produce any injuries sufficient to cause tetanus. Of the entire series of this year there seems to have been none attributed to paper caps. The toy pistol that most frequently causes tetanus is the flimsy, single-barrelled device, built to fire 22-caliber blank cartridges. It is of extremely cheap construction, selling for 10 to 25 cents generally. Very few cases are due to bursting of the weapon, as seems to be thought by some, but most of them are entirely due to the carelessness of the users, who get their hands in front of the muzzle at the time of the explosion. This accident is favored by the shortness of the barrel, the manner of loading, and the frequence with which the pistol gets out of order through fouling or poor construction. Many of the accidents occur when the pistol is held in both hands in trying to overcome some defect in the mechanism. Many accidents, however, were produced by the better grade weapons, both 22-caliber revolvers, and even by larger caliber weapons. The added complication furnished by the revolving mechanism gives many opportunities for accidents, but their greater expense keeps them out of the hands of small boys to a considerable extent. Of the remaining cases not caused by blank cartridges by far the greater part (17) were due to the explosion of fire crackers, usually giant crackers that lacerated the hands

The murderous toy pistol.

severely. There were also a few from cannons (5), and from burns with fireworks. This subject will be considered further in discussing the etiology of Fourth of July tetanus.

Location of the Wounds.—That nearly as large a proportion of wounds occurred on the hands as were caused by blank cartridges is to be explained as effect and cause. Most frequently, as before mentioned, one hand was placed in front of the muzzle accidentally, and received the wad oftenest in the palm of the left hand. The left forefinger and thumb were next most frequently injured. Not a few boys, however, deliberately placed the muzzle of the pistol against the hand and fired it, supposing that since it contained no bullet it would do no harm. Other boys were shot by their playmates in struggles to obtain possession of the plaything, or in attempting to frighten one another. The greater frequency of tetanus in wounds of the hands is probably not due to a greater danger in such wounds, but to their more common occurrence. Tetanus is as frequent after wounds in other parts of the body as we should expect it to be if occurring in proper ratio to the frequency of location of wounds of these parts, but no figures can be obtained on this point. Tetanus has followed wounds

of the leg, thigh, breast, abdominal wall and even of the mouth.

Duration.—The duration of the disease and its period of incubation in Fourth of July tetanus is very short. We are accustomed to consider, on good grounds, the ninth day of incubation as the turning point in estimating prognosis in traumatic tetanus. Cases with a shorter duration than that seldom recover, whereas, the more prolonged the onset is after the ninth day the better the outlook. By far the majority of the boys with Fourth of July tetanus have not only completed the incubation before that time, but have also completed the disease, and are dead. An incubation of but four or five days, with a duration of the disease of 24 to 72 hours is frequent. We are compelled to believe that incubation is shorter in small boys than in adults, for there seems to be in a rough way such a condition indicated by the figures for this epidemic. Presumably, the tetanus bacillus grows as rapidly in a child as in an adult, and, as it requires less of its toxin to saturate the nervous system of the child, the disease and the termination come sooner. But in any event it is evident that Fourth of July tetanus is of an extremely virulent type, with a short period of incubation and a brief duration. Its virulence is still more fully attested by the results, for recovery is remarkably seldom, so far as it has been possible to learn. In the table cases have been indicated as recovering only when definite information to this effect has been received. A number of cases that were reported as recovering, and also some the outcome of which was never reported, have been left blank. Only 7 have been definitely reported as entirely recovered. Undoubtedly there have been other recoveries, for cases that get well are not so certain to get into these statistics as those that die, but at the best it seems probable that the mortality is more likely to be above 95 per cent. than below it; certainly it is higher than 90 per cent. Whether this extremely high death rate is due to a slight resistance in children, or to a particularly virulent type of infection can not be estimated at this time, but probably both factors exist. Antitoxin was used freely, in several cases intracranially, but in general with little effect. The cases that did recover nearly all had antitoxin, but so many more had it without effect that we believe that it was, as a rule, of little assistance because administered so late in the disease. The chief exception is furnished by two patients of Luckett at the Harlem Hospital, New York, that recovered after the use of intraspinal injections of antitoxin. Luckett lays emphasis on the drainage of as much as possible of the toxic cerebrospinal fluid before injecting the antitoxin.

THE CAUSE OF FOURTH OF JULY TETANUS.

The reason for the existence of Fourth of July tetanus, as we may class these particular cases, is by no means settled, although its determination might seem easy. The question seems to have sifted down to the proposition that the bacilli either are or are not present in blank cartridges. If the former is true it is a simple proposition. But if they are not in the blank cartridges, there are several explanations for the frequency with which the wounds they produce are followed by tetanus to be considered.

The following facts speak in favor of the presence of the infectious agent in the blank cartridge: 1. The remarkable frequence of tetanus from blank cartridge wounds compared with its occurrence after other forms of injury. This has become apparent to everyone. None of the other Fourth of July injuries compares with it, and, although it is impossible to learn in how large a proportion of blank cartridge wounds lockjaw results, yet the impression is obtained that the famous rusty nail wound is far less often the cause of tetanus in proportion to its occurrence. 2. While the opponents of the view of the infectious nature of the blank cartridge consider the dirty hands of the wounded child the source of the organism, yet wounds of other parts are often the site of lockjaw. In the cases in this year's epidemic there are several of wounds of the leg and thigh, a few of the abdomen, one of the female breast, and one of the mouth, in all of which the conditions are quite different from those in the case of wounds of dirty hands. 3. The bacteriologist of the Board of Health of Newark, N. J., has presented the following report:

NEWARK, N. J., July 2, 1903.

To the Honorable Board of Health, Newark, N. J.:

Your attention is respectfully invited to the fact that bacteriologic examination of samples of two different makes of blank cartridges has been made at the Bacteriological Laboratory during the past week with the result that among other germs present in the contents of the shells the bacilli of tetanus were found in large numbers.

The tetanus bacilli found are so typical in shape and the odor so characteristic that there is very little doubt of their identity.

The samples examined were purchased in the open market and the cartridges selected promiscuously from the contents of the boxes.

The frequency with which lockjaw follows accidental wounds received by the explosion of blank cartridges may possibly be explained by the presence of these germs in the materials used in the manufacture of the cartridges.

Further examinations will be made to determine if the tetanus bacilli are constantly present, and also to find whether the germs are in the explosive or in the paper wads used.

R. N. CONNOLLY, M.D., *Bacteriologist.*

If this report should be substantiated, as we shall further note, it stands alone in opposition to many other investigations. So far, we are informed, no inoculation experiments have been made, and organisms producing gas, and morphologically similar to the tetanus bacilli, have been described by Wells in blank cartridges, but they were non-pathogenic.

4. Several possible sources for the bacilli have been suggested. One is that the wads are made out of old rags, of straw swept from stables, or other dangerous material. Another is that they come from the saltpeter, which has been insufficiently purified after being obtained from its source from the droppings of bats in caves, etc.

Opposed to the view that the tetanus bacillus exists in the blank cartridge are the following facts:

1. Numerous careful investigations have been made of this possibility by different investigators, examining all the makes of ammunition on the market, during different years, in different cities, and by different methods, and all of them report unanimously (with the single exception noted) that they have never detected tetanus

bacilli. The investigations that we have found published in available literature are as follows:

TABLE 3.

Name.	Year.	Number Examined.	Method.
Wells	1899	200	Culture and inoculation.[1]
Taylor	1899	135	Culture.[2]
Wells	1900	50	Culture and inoculation.[3]
Boston City Health Dept.	1900	350	Culture and inoculation.[4]
LaGarde	1902	24	Culture and inoculation.[5]
Total		759	

A total of 759 blank cartridges have been examined during three years, and in not one has tetanus bacilli been found. It seems highly improbable that so many cartridges can have failed to contain bacilli if they are present in blank cartridges often enough to explain the frequent occurrence of tetanus after the wounds they produce. A possible source of error lies in the frequent occurrence of organisms resembling more or less closely the tetanus bacillus. These have been described in blank cartridges by Wells and by Bain;[6] each describing a different organism, both of which have considerable morphologic resemblance to the bacillus of tetanus, and also resembling it in being anærobic, so that they might readily be mistaken by a casual examination of smears from the pus or of anærobic cultures. In cultures, however, they show certain differences from the tetanus bacillus, and they are nonpathogenic. This may explain the positive finding in Newark, in which animal inoculations were not made.

2. By no means all of the Fourth of July tetanus cases are produced by blank cartridges. In this year's epidemic among the cases for which we have been furnished with a statement of the method of production, nearly 10 per cent. have been ascribed to other sorts of injuries, where any cause is mentioned at all. Of these, exploding giant crackers are the commonest cause. Of course, these offer much the same possibilities for contamination as blank cartridges, if not more. However, LaGarde, who examined the powder and paper from 30 fire crackers, representing six different kinds, failed to find the organisms. Explosions of cannons, rockets and other forms of fireworks have all caused fatal tetanus.

3. At the same time that tetanus is occurring from Fourth of July injuries it is also resulting from other injuries in the same places. Wells[7] has compiled statistics of the annual tetanus cases of New York, Chicago and Washington, and finds that there is a seasonal curve, the greater number by far occurring in summer. June, for example, furnishes nearly as many deaths as December, January, February and March together. In other words, Fourth of July tetanus accidents come just at the time of year when tetanus is most prevalent. There have been included in our tables a number of cases of tetanus resulting from other than Fourth of July accidents, and, therefore, not included in the summary, which shows that tetanus bacilli are widespread at that time, and may be inoculated from any sort of injury. It is interesting to note that the states with the greatest number of blank cartridge cases, Pennsylvania and Ohio, also furnish the largest number of cases of tetanus from wounds not related to the celebrations of the Fourth. A few special cases of Fourth of July tetanus that are of significance in this connection may also be cited:

A boy in Chicago, running to get away from a cannon that was about to be discharged, fell and ran a nail into his hand. Tetanus followed and caused his death.

In Pittsburg a boy was playing with a toy pistol under a bridge, when a trolley car running over it jumped the track and fell some distance to the ground, killing several passengers. The boy was not injured, but was so frightened that he caught his hand under the descending hammer of his pistol and received a small cut from which fatal tetanus resulted.

A boy in Minnesota, while trying to enlarge the bore of his pistol with a file, drove the tool into the palm of his hand, the wound causing death from tetanus.

In Washington, D. C., where 4th of July tetanus is very uncommon, presumably because the laws are enforced, a young man with a chemical turn of mind, constructed an amateur Mt. Pelee by erecting a mound of earth over a collection of chemicals. The explosion shattered the glass containers and drove several pieces of glass, more or less covered with dirt, into his body. Fatal tetanus followed.

In Rockford, Ill., a boy loaded a toy pistol with dirt and pebbles, and shot the contents into his hand. A pebble was removed from the hand, but no wad, after the onset of tetanus.

These cases are but samples of many that go to show that tetanus bacilli are present in the street dirt and about the persons of the celebrators. As further evidence we have the fact that in all the places where Fourth of July tetanus occurs the disease is more or less endemic, and if not seen in practice it will be found to occur in horses. In studying the Chicago epidemic no difficulty was found in demonstrating the organisms in street dirt in 1900.

4. The manufacture of blank cartridges is so conducted as to cause little chance for infection with the tetanus bacilli. While, of course, no special precautions are taken to keep out the organisms, and, therefore, the materials are by no means sterile, yet there is no step in the process that would particularly favor the presence of tetanus bacilli, as, for example, would be the case if hair were used, as in the wadding of shotgun ammunition. The pasteboard wads of the blank cartridges have always aroused much suspicion, both because they are so often found in the wounds, and because we have distinct impressions of the sort of material the "rag man" used to collect for the purpose of making paper. We are indebted to the Union Metallic Cartridge Company for the following description of the process:

This board is made of new rags and new cuttings of paper, and also sulphite wood pulp. The rags are cooked in soda ash and lime under high pressure, in a rotary boiler for six or eight hours. They are then put into a washer and thoroughly washed for a couple of hours or more and bleached with chlorid of lime and alum. The paper stock is also cooked in the same manner, but without chemicals being put with it—simply boiled under high pressure. The rags after being boiled are let down into draining chests and thoroughly drained before being mixed with the paper stock in the manufacture of the board. No clay whatever is put into the board, and the coloring matter is a very weak solution of anilin blue, the color being set with a little alum. Generally this board is dried in the loft, although when necessary heat is applied.

It is evident that if even so resistant an organism as the tetanus bacillus were present in the original ma-

terial, and there is no apparent reason why they should be present, they could not survive such treatment as here described. As to the powder, LaGarde says:

> The purity of powder is assured by the high degree of heat to which the three ingredients of the powder are subjected before being incorporated in the form of an explosive compound. These ingredients, as is well known, are, saltpeter, 15 per cent.; sulphur, 10 per cent., and charcoal, 75 per cent. In refining saltpeter the saturated solution of the crude material is heated to a temperature of 250 F., the sulphur is fused from the crude brimstone, in order to remove extraneous matter, and the charcoal is obtained from willow wood after being subjected to a high temperature in a retort.

In all the studies of blank cartridges cited above the powder has come in for investigation, and tetanus bacilli never found. If impure saltpeter were a source of danger we should look for the greatest trouble to come from firecracker explosions, for they are, or at least were, prepared with a much more crude powder than the blank cartridges.

The shells are also subjected to a high temperature and to immersion in baths of strong acid and alkali. They, too, have been often examined with negative results.

On the other hand, it is to be borne in mind that there is not sufficient heat generated in the discharge of the cartridge to destroy tetanus bacilli if they were present in the powder or wads. LaGarde has shown, experimentally that the organisms when placed on the wads or in the powder of 22-caliber blank cartridges are not destroyed by firing. Such infected cartridges, when discharged in such a way as to injure rats, caused nearly all to die of tetanus.

From all these facts we may conclude that there is no convincing evidence that blank cartridges contain tetanus bacilli, except possibly as a rare contamination when they have been exposed to dirt. On the other hand, there is ample evidence to indicate that tetanus bacilli are present in the street dirt and on the persons and clothing of the injured people. The most reasonable assumption at this time is, therefore, that the organisms are carried into the wounds from the surface at the time of the accident. This has been the conclusion of LaGarde, Wells and all others who have studied this subject experimentally.

The question to be decided is, therefore, why blank cartridge wounds should be peculiarly dangerous, and to this the most plausible explanation seems to be twofold. 1. The wound is received at a time of year when tetanus bacilli are most prevalent, probably because the street dirt that contains them is widely scattered, instead of being frozen solid as in winter, or wet as in spring. It is also received at a time when the victim is usually particularly well supplied with this dangerous dirt. 2. Blank cartridge wounds offer the most ideal conditions for the development of tetanus of any common wound with which we are familiar. If we consider what are ideal conditions for the development of tetanus it will be seen how true this statement is. Ideal requirements call for the following conditions:

(a) First of all the wound should be penetrating, so that anærobic conditions may obtain. Blank cartridge wounds are nearly all penetrating, especially those that cause tetanus. Often, indeed, they pass through the palmar fascia, and usually the track is well sealed after them.

(b) The penetrating object should carry in any surface dirt present. A nail wound, with its well-known tendency to cause tetanus, can not compare with the blank cartridge in this respect. The wad, usually striking perfectly flat, has a great tendency to punch out and carry before it a disk of skin or of clothing that may oppose it, which a nail would push aside.

(c) Resistance of the tissues should be lessened. Here, especially, the blank cartridge wound surpasses the nail wound. Tetanus bacilli or spores, washed free from toxins, and injected with a minimum injury to the tissues can be destroyed in large numbers by the tissues or blood. Blood clots in a wound are particularly favorable, places for infection. Lwowitch and Strich have each shown that tetanus inoculation in animals is far more effective if made into a hematoma than if introduced subcutaneously, and the latter further found that gunshot wounds were much better inoculation places than even hematomas, the symptoms appearing twice as soon and death ensuing earlier. LaGarde found that burning tissues made them most favorable sites for tetanus inoculation. All animals inoculated in a wound made by burning died from doses of tetanus bacilli that were without effect when inoculated into incised wounds. Therefore, the burning, tearing and bruising of the tissues in blank cartridge wounds is of particular import, and no other sort of wound produces these conditions so well. This susceptibility of burned tissues probably explains the not uncommon appearance of tetanus in burns, whether of Fourth of July origin or not, a fact somewhat at variance with the general rule that tetanus bacilli will not live in surface wounds exposed to the air.

(d) Other bacteria being present to remove oxygen and to destroy tissue resistance also favor tetanus. Blank cartridge wounds, with their large amount of introduction of extraneous material, practically always cause mixed infection.

THE PREVENTION OF FOURTH OF JULY TETANUS.

Our chief object in this work has been the establishment of a basis for consideration of Fourth of July tetanus from the standpoint of preventive medicine. It is for this reason that we have considered to such an extent the question of the source of the infecting tetanus bacilli that cause the disease. We confess that at first it seemed to us that the bacilli *must* be present in blank cartridges, and had that been the case the prevention would have been a simple matter.

In the absence of any positive demonstration of their presence in the cartridge, the other facts that have been recounted concerning these particular wounds seem sufficient to explain their peculiar danger. It is, therefore, evident that we can not secure safety by some modification in the method of manufacture, a thing the manufacturers would be willing to attend to promptly to escape responsibility. The only way to prevent Fourth of July tetanus that can be successful must prevent the use of blank cartridges altogether. The ideal way would be to attack the source of the evil, by prevention of manufacture and importation into the country of blank cart-

ridges. We know of no essential purpose that blank cartridges serve—their occasional use in melodrama and in starting foot races could easily be accommodated in some way not calling for an annual sacrifice of several hundred lives. Presumably, this would be distasteful to the manufacturers, and it is impossible to say in advance what their attitude would be if they were brought face to face with the proposition that they are the sole cause of the unnecessary death of over 400 boys in the United States every year. It would be pleasing to believe that sound business men, such as we know them to be, would be willing to forego a certain amount of income, donating this, if you please, to the cause of public safety. Might it not be well for the American Medical Association to present this proposition in all its significance to the manufacturers? What the possibilities are for legislation in this direction we are unable to say. Might not this matter of the prevention of Fourth of July tetanus be a proper theme for action by the Association at the next annual session?

As for the manufacture of toy pistols, much the same things are to be said. These flimsy contraptions serve no good purpose, and outside of their relation to tetanus there is one particularly bad feature, namely, their tendency to cultivate in young boys the habit of carrying pistols. "The hip pocket arsenal" is one of our great American vices, responsible for many unnecessary homicides and accidents, and it is not imaginative to consider that putting blank cartridge pistols in the hands of boys is a contributing factor to its prevalence and perpetuation. However important the toy pistol itself may be in causing tetanus, it is secondary to the blank cartridge, for many accidents result from ordinary revolvers, and, of course, the cessation of the production of the cartridges carries with it the end of the toy pistol.

Lacking any immediate means of terminating the production of blank cartridges, and while hoping for its speedy accomplishment, we have another tried and proven method of checking these accidents by stopping their sale in each individual city or town. The feasibility of legal intervention here has been shown, for most of the larger cities have ordinances covering this matter more or less adequately, although many of them seem to have become lost through disuse. However, they do exist, and where lacking can be readily provided, for they come into the proper province of the city authority. The difficulty lies in the enforcement. For example, in Chicago such an ordinance is well known to exist, occasional prosecutions having been made under it. Almost annually a mayorality proclamation has been made concerning Fourth of July injuries, and the necessity of suppression of the sale of toy pistols and blank cartridges, and the police are ordered to enforce this ordinance. Yet there is no difficulty in procuring blank cartridges and toy pistols, as we have learned by experiment. This year, when the tetanus deaths began, long after the Fourth had passed, orders were given the storekeepers not to sell toy pistols, and it was found that some dealers were obeying the law. However, there were others who still sold them, with the admonition not to say anything about it, as "the coppers have given us orders we can't sell them." Not until numerous prosecutions have been made can the dealers, chiefly proprietors of small confectionery and notion stores, be frightened into obeying the law. In Philadelphia some attempts have been made in this direction, and the newspapers report that the father of one of the dead boys has brought suit against the man selling the pistol. The inefficiency of municipal authorities is particularly seen in Philadelphia, where a full warning had been given by an epidemic of tetanus after the Decoration Day celebration. Deaths from this celebration were still occurring when the epidemic of the Fourth began. Here, if ever, was the presence of an example and a warning to stir some one to action, but that this action was not forthcoming is evident from the development of perhaps the worst Fourth of July epidemic in the history of the state.

Probably but little can be done by education of the boys themselves. "It isn't Natur'." One writer has remarked that a boy could be shown 200 other boys dying from lockjaw, and that if he were then given a quarter, and the Fourth were coming, he would go out and buy himself a toy pistol and a box of cartridges. This may be exaggeration, but not for all boys. However, there are some who can be reached by instruction, and some sound advice given by their teacher just as school is closing for summer before the Fourth, might save some lives at least.

Education of the parents is evidently called for also, to judge from the number of cases in which the information was given that "the boy's mother dressed the wound herself, thinking it of no consequence." They will probably be reached best through the daily papers, and we wish again to express appreciation of the efforts that the press, almost as a whole, has made. Some papers have conducted a long campaign with an evident sincerity of purpose that is pleasing in contrast to the attitude that has occasionally been taken in relation to some matters of preventive medicine. One great obstacle lies in the fact that a very large part of the cases occur among the children of the illiterate, which also indicates the value of parental control among the better classes. So long as blank cartridges continue to be sold to children, however, education of parents to do their best to prevent their use, and to secure proper treatment of the wounds they may produce, must be continued.

And, lastly, there is room for improvement in the way in which many physicians care for blank cartridge wounds that come to them. There, unfortunately, exist physicians who do not keep informed on either medical or popular progress, and to whom a blank cartridge wound is a blank cartridge wound, and nothing more. At least there have been many physicians who have seen such wounds shortly after they have been received, who have been content with simply dressing the wound, often without even an attempt to remove the wads and other foreign matter contained therein. And often these physicians have occupied positions in hospitals and dispensaries that would seem to indicate their possession of more than average information. With the excellent knowledge that we possess of the bacillus of tetanus and the widespread familiarity with the danger of blank cartridge wounds, such inefficient treatment is censurable. Bain has well demonstrated the efficiency of thorough

surgical technic in preventing tetanus by his report of a case of blank cartridge wound so treated, in the secretions of which tetanus bacilli were demonstrated, and yet tetanus did not occur. Prophylactic use of antitoxin is also to be urged where it is available. Veterinarians have accumulated ample evidence of its efficiency as a prophylactic, which is in marked contrast to its slight power as a curative agent. In man there is also plenty of evidence that it is equally effective, and altogether without harm. It has been used by Taylor for prophylaxis in blank cartridge wounds with complete success. He has used it in many cases, always without harmful results, and with no tetanus, although in other cases where antitoxin was not used tetanus has

most apparent to the public are those which occur during the celebration. Aside from tetanus in the celebration of the Fourth of July this year 60 deaths were caused, 10 persons made blind, 75 persons lost one eye, 54 lost hands, arms or legs, 174 lost one or more fingers and 3,670 received other injuries, making a total of 3,983 persons injured. Adding the deaths from tetanus and from other causes, 4,449 persons are dead or injured. These facts are embodied in Table 4.

This appalling summary is not given as an item of sensational news, but to arouse efforts in the line of prevention. The table speaks for itself, and deductions from it are easily made by anyone. It will, however, add to the value of the table to note the following facts:

TABLE 4.—SUMMARY BY STATES OF JULY FOURTH CASUALTIES.

followed. His method has been to follow thorough surgical cleansing with injection of 5 to 10 c.c. of antitoxin, repeated in a few days if the wound does badly.

A great help in any future efforts to stop this annual epidemic will be the collection of complete data of all the cases, in a more official and complete manner than it has been done in this paper. This must be the work of either municipal or state boards of health. Such an inquiry has already been started by the Michigan State Board of Health, and it is to be hoped that other states will also take up the matter. There is also need for further study of blank cartridges, since their freedom from tetanus bacilli is still undetermined.

B. DEATHS AND INJURIES ASIDE FROM TETANUS.

Above have been discussed the cases of tetanus incident to the Fourth of July celebration, but the injuries

SOURCE AND RELIABILITY OF STATISTICS.

A detailed list has been compiled of the 4,449 persons dead or injured, giving the name or description of each, the nature of the injury and the cause. These are classified under cities and states, and from this list Table 4 has been prepared. The facts were furnished by the newspapers from the various sections of the United States. Only such cases have been listed as presented names and data, or, in the absence of the name, a case has been included when it bore such marks of identification that it could be distinguished from other cases in the same city. All doubtful cases have been omitted.

Concerning the number of injuries here reported, it is safe to say that not two-thirds, perhaps only one-half, of those occurring in the United States are here presented. In evidence of this fact, it is worthy of note

that the large city of Washington, D. C., is represented by but one case. The newspapers of Philadelphia stated that 500 people were injured in that city in the Fourth of July celebration, and that 380 received hospital treatment; in comparison with this accounts of only 151 were received. In another city the newspapers stated that there were 90 persons injured; the table contains 10. Further, it is evident that the absence of statistics in certain states can not be explained on the ground that accidents did not occur.

This table contains only deaths and injuries directly due to explosives of one kind or another. For example, we have not included several deaths which occurred from fright and from heart disease, nor several deaths occurring in runaways caused by firecrackers. Another death not included is that of a butcher who committed suicide to escape the noise and turmoil incident to the day. Other injuries not included may be illustrated by the following: In the endeavor to escape from firecrackers, cannon, etc., after they had been lighted, several people sustained fractured bones and other severe injuries; one man was killed by a train while putting a torpedo on the track, and a boy while shooting firecrackers on a roof fell five stories and broke his leg.

Because of the paucity of newspaper accounts in certain communities, it may easily have occurred that some of the injuries here cited eventuated in death, blindness or loss of members, inasmuch as the accounts have stated that "the injuries may prove fatal," or "the physicians give little hope of saving the boy's sight."

In the tabulation of injuries, where one person lost an eye and a finger, for example, he was counted in but one column; therefore, the total number of persons who lost fingers exceeds the total at the foot of the table.

Under the heading of "other injuries," it is worthy of note that the following are included: Fracture of the skull, of the leg, of the arm, etc.; loss of hearing, loss of patella, loss of nose, loss of ear, penetrating wounds of lung, brain, abdomen, etc. The majority of injuries, however, were wounds and burns of the face, eyes and hands. All accidents are included that were incapacitating or that required medical attention.

It may occur to someone that perhaps some of the minor injuries recorded in Table 4 later developed into tetanus infection and resulted in death. This is the case. A careful comparison, however, of the cases in the tetanus list with those in the list of injured shows that comparatively few of the former appear in the latter. For this reason and because the list of injured is grossly incomplete, the fact that some few persons are really counted twice in the total number of persons dead or injured is not very important. The reasons for the absence of certain tetanus cases in the list of injured are two: The list of injured is incomplete, and—a very instructive point—the tetanus cases were, in many instances, caused by wounds too trivial to be reported or to be included in the list.

DEATH AND INJURY ABROAD.

These statistics are concerning the United States. Although the national holiday is celebrated in other lands by some few persons, only the following cases of death or injury have been reported: In Ceylon, a British gunner was killed and another was injured by a cannon while firing a salute in honor of the United States. In Canada a boy was injured by a firecracker.

THE CAUSE OF INJURY.

Specification of the causes of tetanus shows that 363 cases were due to the blank cartridge or toy pistol, while all other causes together were responsible for a total of only 29 cases. In comparison with this, the causes of other injuries are divided more evenly between the blank cartridge, the firecracker and the other uses of powder. To make it exact, the blank cartridge caused about 33 per cent. of the non-tetanus injuries, but caused over 92 per cent. of the cases of tetanus.

In other words, the danger of accident in the use of the blank cartridge may not be much greater than from the use of other means of celebration, but the danger of tetanus is shown to be extraordinarily greater when the blank cartridge is used. To make the statistics of more value, it would be interesting, if the facts were available, to know what proportion of those engaged in celebrating do so with the toy pistol, how many with firecrackers, how many with cannon, etc. The injuries from firecrackers are largely from the large variety, from their accidental and unexpected explosion, and especially from the carelessness of persons who held them in their hands while they went off. Many crackers are loaded with dynamite, and persons fail to realize the power hidden in them. Gunshot injuries (bullet wounds) are notably in excess in the cities, because of the number of persons in the cities who carry weapons. The injuries from toy cannons, powder burns and fireworks (for evening display) may be taken as such as have occurred for many years. The increase in injuries of late years may be assigned to the great increase in use of the cannon-cracker and the blank cartridge. These were deadly additions to the boy's armament, and they together caused 2,461 of the 3,825 injuries for which causes were assigned, or over 64 per cent.

In explanation of the column headed "powder and fireworks," it may be said that this includes all the causes not in the other columns. To summarize: Nearly one-half of these injuries were caused by the use of powder, about one-third by fireworks (for evening display), and the remainder of cases in this column were from miscellaneous causes, such as torpedoes, paper caps, chemicals, matches, etc.

The first column of causes, that of blank cartridges, includes blank cartridges and toy pistols, also a very few cases of injury from the use of the cartridge cane. These latter cases are included in this column because they use the blank cartridge or small metal dynamite caps, and the explosion and the injury are almost identical with those caused by the discharge in the toy pistol.

Since the cause was not stated or was ambiguous in the accounts of many accidents, the total number of cases under the heading of causes is less than the number of persons dead and injured.

The causes were plainly stated for 58 of the 60 violent deaths and are as follows: Blank cartridges, 11; firecrackers, 14; cannon, 14; gunshot wounds, 9; powder burns or explosions, 4; fireworks, 3; torpedo, 1; caps, 1; matches, 1. A number of these fatal wounds and many injuries were received by innocent passersby.

SATURDAY, AUGUST 29, 1903.

THE FOURTH OF JULY CELEBRATION.

The Fourth of July, with its casualties, has come and gone, and we can now count up the cost. Elsewhere in this issue we give a summary of the accidents, so far as reported to us, and a special analysis of the tetanus cases. The truly formidable showing made is well worthy of serious contemplation. We like to consider ourselves a smart people, but there are some facts that are troublesome to this conceit, and the present method of celebrating the nativity of our national independence is one of them. True patriotism is an excellent thing, but no one serves his country by making his nation's birthday a day of peril to life, limb and property. It would be a rash calculation that would estimate that even 50 per cent. of those celebrating the Fourth have any real spirit of patriotism in the act. All that is wanted by them is to make a noise and indulge in a license not allowed on other days. An English writer whose works used to be very popular with boys says, in effect, in one of them that he can gauge the decadence of a people by the amount they spend for fireworks. While we would not exactly endorse his utterance, we certainly consider such expenditures as we have each Fourth as very far from being an index of national intelligence. It is, in fact, a blot on our record. It would be better to abolish the Fourth of July as a holiday, and to keep it only as a glorious tradition, sadly dimmed by recent experience of its celebrations, than to continue the annual sacrifices we now make to its memory.

Two facts stand out in the consideration of the annual holocaust—one is that there was no lack of warning or even of legal prohibition in some sections from which the worst experiences are reported. In Pennsylvania, the state which records the greatest number of toy pistol tetanus deaths, the sale of toy pistols to boys under 16 seems to have been illegal and prosecution of dealers is being urged by the State Board of Health. Lawbreaking followed by homicide, for this is nothing else, is a pretty serious matter, as some of these unscrupulous commercialists may find it. The other fact is that the victims of this annual tragedy are mostly immature boys whose discretion is always questionable and who should be protected by law, if not by parental control, from just such possibilities. It is a massacre of the innocents often in one, and sometimes in the other, sense of the word. "Butchered to make a Roman holiday" is a favorite old quotation that may yet come to need a modern adaptation.

We trust that our readers will utilize the statistics we present this week as an argument for more active repression of the lawlessness which accompanies the annual celebration of our national independence. Warnings have not been brilliantly successful in the past; but by persistent and frequent repetitions they may accomplish something each year, until finally the annual sacrifice is done away with. Four hundred and sixty-six lives sacrificed, 10 persons made totally blind, 95 eyes lost, beside 500 other persons maimed and disfigured for life, is a record that calls loudly for justification, and, finding none, demands termination.

Reprints of the matter, with the tables, will be supplied in any quantity at a nominal price, and should be ordered at once. These may be useful to distribute among those whose duty it is to prevent the dangerous methods of celebrating, viz.: city aldermen, mayors, etc., etc. Any corrections, additions or suggestions as to this matter should be sent at once.

THE PREVENTION AND TREATMENT OF FOURTH OF JULY TETANUS.

We now turn to the chief factor in the mortality—tetanus. With over four hundred deaths from lockjaw as a result of the demonstration of a single Fourth of July—more than the entire loss of life from wounds in a good-sized modern battle—surely it is time for something to be done, for there is no evidence that this year's mortality is any greater than that of other years. The astounding total of 415 cases of Fourth of July tetanus, however, is probably below the actual number, for we have every reason to believe that many more cases have been omitted from our statistics than have been erroneously included. That the total is astounding is probably because this represents the first attempt, with which we are acquainted, to collect the accidents of the entire country into one group. That such a summing up of the fearful results of a Chinese celebration of an American holiday may stir up enough feeling in the proper places to lead to some action toward its termination is our motive and hope in undertaking this work.

There are several parties involved in the crime. First, there are the municipal authorities who have before them laws directed toward controlling the dangerous forms of celebration, which they make inefficient or make no efforts to enforce. Secondly, there are the dealers in toy pistols, who, for the sake of a very trivial income, violate the laws that exist in most cities against the sale of firearms to minors. These two must be considered the primary culprits, for they are acting in violation of laws that have been made for the express purpose of preventing this very unnecessary mortality. Manufacturers of blank cartridges and toy pistols are simply complying with a popular demand, and are not culpable in the same degree as they are violating no laws, although they must appreciate the fact that they hold in their hands the essential means of continuing or ceasing the trouble. As for the parents of the boys, they are usually either ignor-

ant of the actions of the boy, or of the danger of his pastime, and they are often completely unaware of the danger of the blank cartridge wounds.

After going through the reports of all these four hundred cases, and reading all procurable lay press comments and explanations, it seems to us that the only method that offers much hope of success must be directed at the primary seat of the trouble, the blank cartridge itself. Arraignment of municipal authorities and prosecution of dealers in toy pistols and blank cartridges can have but local effects, and the trouble is universal. Our figures show that the blank cartridge is responsible for such a very large proportion of all the cases, over 90 per cent., that control of this danger will leave the rest a relatively simple matter. But how are the blank cartridges and toy pistols to be removed from the Fourth of July program? There are, so far as we can learn, but four manufacturers of blank cartridges in the United States and one in Canada. Whether they can be prevented from manufacturing or importing the perfectly useless blank cartridge or not is a matter to be determined by the proper legislative body. If this can be accomplished we shall be rid of the greatest danger, if not the greatest nuisance of the Fourth. If national intervention is impracticable it is certain that state legislatures can prohibit the sale of blank cartridges and toy pistols within their boundaries—it certainly is as proper a subject for legislation as the cigarette, and there probably would not be as great opposition by commercial interests. Some of the state boards of health are already taking up a study of Fourth of July tetanus, and the results obtained will be valuable, especially as material for directing legislative action.

Until the sale of blank cartridges has been stopped there is much to be done in the way of popular and professional education. Parents must be taught that toy pistols are to be kept out of the hands of children. The fact that a large proportion of the cases of tetanus have occurred in the children of the poorly educated is an indication that parental control is not without effect. They are also to be taught that every Fourth of July wound possesses great possibilities of causing lockjaw, and requires skilful medical care. This instruction they will receive chiefly from the daily papers, but in smaller communities much can be done by the physician. The need of some means for popular information in preventive medicine is illustrated again in this case. And in turn it is to be expected that the family physician will appreciate the gravity of the situation when a boy is brought before him with a blank cartridge wound, no matter how trivial that wound may seem to be. Not only does it demand thorough surgical cleansing, but also prophylactic injection of antitoxin. Fortunately, the incubation of tetanus is so long that unless the case occurs in some unusually isolated community, antitoxin can be procured before the disease has manifested itself, for then, in most cases, serum treatment is of no avail.

It is evident that the treatment of tetanus must be prophylactic, for the returns from these cases of the Fourth show how little has been accomplished in the direction of cure. But a very small percentage of recoveries, apparently under 5 per cent., has occurred, in spite of quite general use of antitoxin. It has been well said that the patient who is just showing tetanic symptoms is not beginning to have tetanus—he is beginning to die from it. The spasms of tetanus are practically the death agonies of an infection that has existed several days before their onset, and experience has shown that tetanus antitoxin is then of but little value. We may look to Fourth of July tetanus to furnish us with much information concerning the treatment of the disease, since these cases constitute such a large and concentrated part of our experience, but so far the results have only served to emphasize the importance of prophylaxis and the futility of curative measures. Surgeons who have carefully cleansed and drained blank cartridge and fire cracker wounds have had few cases of tetanus; surgeons who have also given antitoxin while the wound was fresh have had none.

Perhaps the most promising suggestion in the way of curative treatment is that of Luckett,[1] who has reported two recoveries, and informs us of two more yet unpublished. This is the intraspinal method of antitoxin administration, which has already been used somewhat in Europe. It is much less dangerous than the intracranial method, and seems much more logical. The chief manifestations of tetanus come from the injury of the anterior horn cells of the cord—not from the cerebral cortex where the antitoxin is introduced in the intracranial method. There is much reason for believing that the toxin reaches the cord along the nerve sheaths from the point of injury, rather than by the blood, and it has been shown that the cerebrospinal fluid is more toxic than the blood serum in tetanus. Therefore, intraspinal injection permits of application of the antitoxin where it would seem to be of greatest value, and it also gives an opportunity for letting escape as much as possible of the highly toxic cerebrospinal fluid through the needle, before injecting the antitoxin. On this last point Luckett lays much stress, and it would seem theoretically to be an important factor. At any rate, the brief use of this method has given such excellent results, and it is based on such sound principles, that it should be given widespread trial.

RECENT WORK ON CELL POISON OF ANIMAL ORIGIN.

Few available tissues of the body remain for which some one has not produced, or attempted to produce, a specific cytotoxin by immunization. Théobari and Babès have the latest cytotoxin—a gastrotoxin, produced by injecting the mucous membrane of the cardiac end of the stomach of dogs into goats. A part of their method is unusual, in that they suspended the emulsion of tissue

1. Medical News, April 18, 1903.

in 1 per cent. salicylic acid solution, instead of the normal salt solution which is ordinarily used. The reason for this is not stated, but probably it was to combat the bacteria which no doubt were present in the mucous membrane. Three to four injections of the emulsions, given at intervals of ten to fifteen days, gave a fairly toxic serum, of which 15 to 60 c.c. were injected into the jugular veins of dogs. By way of control, it was found that 60 c.c. of normal goat serum injected similarly produced no symptoms in dogs. Injections of small amounts of the toxic serum (15 c.c.) caused vomiting and hemorrhage into the intestines, some of the animals recovering and others dying. Larger amounts of a strong serum (60 c.c.) caused death in ten to twenty minutes. Necropsies showed lesions limited to the cardiac portion of the stomach and the small intestine. These portions were congested and blood was present in the bowel. Histologically, the peptic glands showed a condition of the cells seen in hypersecretion, particularly after large doses of the serum had been given. Many of the chief cells and lateral cells had lost their granulations and the former are stated no longer to have contained pepsin. The cytoplasm of many cells was uniformly cloudy. In Lieberkühn's glands the cells were often cloudy, and the capillaries underlying the affected surfaces were widely dilated. They concluded that the chief degenerative changes were in the lateral cells. The authors are unable to explain that the small intestine and cardiac end of the stomach should be attacked while the pyloric portion and the large intestine were uninvolved.

This work is interesting, and there probably is no reason why the cells of the gastric mucous membrane should not yield a cytolysin as well as other cells. But so far as one can judge from the article mentioned, the work of Théohari and Babès is too incomplete to justify all the conclusions they have drawn. What most arouses suspicion is that they apparently assign the rapid death in some of their animals to the toxic effect of their serum on the mucosa of the stomach, omitting examination (or at least mention) of the conditions in more vital organs. If the action of the immune serum was selective and specific for the epithelium of the stomach and intestines, it is difficult to see how the slight injury to these structures recorded could produce death in fifteen minutes. There is, indeed, sufficient evidence in their report that the serum was not absolutely specific for the cells of the gastric mucosa. The hemorrhages into the bowel probably could not have been caused by any amount of lysis of the epithelial cells. It has been shown by various investigators that hemorrhages may be caused by many toxins, the result apparently of a solvent action on the endothelial cells of the capillaries by special substances — endotheliolysins, Flexner's "hemorrhagin." It is also not excluded in their work that hemolysin and hemagglutinin were not produced by the immunization. In addition, it may be stated that intravenous injections of other cytolytic sera are able to cause vomiting, and bloody stools and urine. It is not improbable that careful examination of other organs in these experiments would have shown pulmonary or cardiac conditions sufficient to explain the sudden death of some of the animals. Workers with immune cytotoxic sera have noted that a fatal pulmonary edema may occur in a few minutes following the intravenous injection of a large amount of a toxic serum. The exact cause of this edema remains unexplained as yet, but it seems probable that it is due to endotheliolytic effects or embolism of agglutinated red blood corpuscles. The study which Kraus and Sternberg made of the tissues of animals killed by injections of immune hemolytic serum, indicate that other cells than those for which the serum is supposed to be specific, may be injured. They frequently found focal necrosis in the liver and cloudy swelling of the kidneys in their animals. On the whole, recent works of immune cytolysins seem to show that attempts at immunization with one type of cell may yield a serum, which is toxic not only for this cell, but for others also—polytropic, rather than monotropic in its action. That is to say, in terms of the side-chain theory, that particular cell, besides having receptors peculiar to itself, also has some which may be found in other cells. Hence, in immunization, antibodies would be produced for more than one kind of cell. Hence the efforts to produce absolutely specific, cytotoxic antiserum may be quite hopeless, even in cases where it is possible to secure for injection cells of one kind only.

Similar results are noted in immunization with bacteria; for example, immunization with the typhoid bacillus yields a serum which, in addition to agglutinating in high dilutions the typhoid bacillus, will also agglutinate the colon bacillus in higher dilutions than the normal serum. To know that this lack of specificity does exist at any rate makes clear how certain bacterial poisons which have a high affinity for certain tissues are able at the same time to injure other tissues, as in diphtheria for instance.

THE AMEBA OF DYSENTERY.

Now that the study of the pathogenic protozoa has become the order of the day, it is reassuring to find that observers trained along zoologic lines are directing more and more attention to the study of these microörganisms. An interesting example of the progress that can be hoped for from studies of this character appears in the recent work of Schaudinn[1] on the life history of certain ameboid organisms. Schaudinn calls attention to the fact that the group of so-called amebæ is by no means zoologically well-defined, and that it doubtless contains organisms of most heterogeneous character with widely diverse life histories and uncertain zoologic affinities. In the course of studies that have extended over a period of eight years on the parasitic rhizopods of the human alimentary tract, Schaudinn has made the important discovery that the ameba present in

1. Arb. a. d. k. Ges., 1903, xix, Heft 3, p. 547.

healthy individuals possesses a developmental history radically different from that of the ameba found in dysentery; and that, therefore, on purely zoologic grounds, the two organisms must be regarded as quite distinct. For plausible reasons the former organism is newly designated by Schaudinn as *Entamœba coli*, and the ameba of dysentery, by a similar change of nomenclature, is called *Entamœba histolytica*.

The ameba of the normal intestine multiplies both by simple division and by a process that used to be termed spore-formation, but that zoologists now denominate schizogony. The latter phenomenon is preceded in *Entamœba coli* by remarkable nuclear changes. In brief, these consist of ordinary reduction divisions, after which a conjugation takes place between two daughter nuclei that have arisen from the same mother nucleus. Mitotic division then proceeds and the protoplasm of the cyst comes eventually to contain 8 nuclei; finally a division of the protoplasm takes place and 8 small amebæ are formed. A close analogy to this singular process has been observed by Hertwig in *Actinospherium*, where a similar conjugation occurs between two daughter nuclei derived from the same mother nucleus.

The process of reproduction of *Entamœba histolytica* follows a different course. Nuclear division of a regular character is entirely absent or at least has not been observed. Instead, a kind of fragmentation of the chromatin takes place, the remnant of the nucleus itself being expelled from the cyst. Small spherical bodies, 3 to 7 microns in diameter, are formed in the cyst, each of these presumably containing some of the finely fragmented chromatin. Schaudinn showed experimentally that these spores of *E. histolytica* were capable of causing serious intestinal symptoms and lesions when fed to cats. In addition to the great difference between the two species of *Entamœba* in their method of reproduction, an important morphologic difference, already dwelt on by Jürgens,[2] is reaffirmed by Schaudinn. This is the stiff hyaline structure exhibited by the ectoplasm of *E. histolytica*. In this species the outer zone of the protoplasm is always sharply delimited from the inner, and it is apparently the possession of this firmer layer that enables the dysentery ameba to thrust its way into the tissues.

The differentiation of the ameba found in dysentery from the form so commonly present in healthy individuals has heretofore proved a matter of some perplexity, and the apparent identity of the two forms in their ordinary phase has in the past given rise to confusion and misunderstanding. Schaudinn's researches will certainly be welcomed by pathologists as tending to establish the complete zoologic independence of the two species. More confidence than hitherto will be felt in attributing to *Entamœba histolytica* a causal rôle for the peculiar dysenteric disease with which it is associated.

2. Veröffentl. a. d. Geb. d. Militärsanitätswesens, 1902, xx, p. 110.

LEMON JUICE AND TYPHOID FEVER BACILLI.

At the end of the year 1902 and during the early part of 1903, much was published in the medical and lay press regarding the action of lemon juice on typhoid bacilli. Reports from the laboratory of the public health department of one of our large cities claimed that "a teaspoonful of lemon juice to half a glass of typhoid infected water is sufficient to destroy the vitality of the contained germs and thus to prevent their production of the toxin or poison which causes typhoid fever." From the same source the suggestion was also sent out that oysters infected with typhoid bacilli could be rendered innocuous by pouring lemon juice over them. These ideas were eagerly taken up by the daily papers, and as a result many people entertain the false idea that lemon juice in water and on oysters protects them from danger of typhoid fever when these are swallowed.

As has been shown by subsequent observations, the juice of lemons possesses no such germicidal power, as these statements would indicate. W. Johnson[1] has found that typhoid bacilli are capable of increase after exposure of 24 hours to a 2 per cent. solution of lemon juice, and after 20 minutes to a 9 per cent. solution. His results are entirely opposed to the newspaper statements of disinfection by a 1 per cent. solution in an hour or less. W. D. Greene,[2] health commissioner of Buffalo, has just published the results of a series of experiments by the city bacteriologist. They were undertaken to determine the germicidal property, if any, of the mixture known as lemonade. The experiments emphasize the necessity of discriminating between simple inhibition and destruction in all tests of germicidal agents. Typhoid bacilli were not killed by exposure of 45 minutes to a mixture of the juice of one-half a large lemon in a glass of water. Greene concludes that lemon juice in the proportion described is not at all to be depended on in rendering polluted water safe for drinking purposes. As to the ability of lemon juice placed on the surface of oysters to destroy typhoid bacilli deep within the body of the oyster we know nothing, but we have every reason to believe that no such result will occur. It was shown nearly 15 years ago by Kitasato that acetic acid in a strength of 0.2 per cent. and citric acid in a strength of 0.43 per cent. would kill typhoid bacilli in 5 hours, and that much weaker dilutions of the acids would inhibit the growth of the bacteria. The results of the tests on which the reports referred to at the beginning of this article were founded had evidently been misinterpreted, and simple inhibition of growth by the lemon juice which was carried over to the nutrient medium mistaken for destruction of the bacteria.

The fate of the lemon as a preventive of typhoid fever again calls attention to the desirability of submitting the results of scientific investigation to medical societies and publications so that they may be substantiated or disproved before they are rushed before the general

1. Northwest Medicine, May, 1903.
2. Bull. Del. State Board of Health, No. xvi, July, 1903.

public. The public, having once learned of an easy way of preventing typhoid fever by simply squeezing lemon juice into water, or on oysters, will not be so ready to return to the more troublesome procedure of boiling water. Thus the results of years of teaching are lost in part at least on the public in a single day. Another unfortunate result of such experiences is that they place the laboratory which makes the mistake in a bad light before the profession, and subsequent reports from the same source are apt to be received with suspicion.

THE RURAL LABORATORY.

Last week we called attention to the practical value of blood examination, and its great importance as a means of diagnosis and to the simplicity of its technic.

But valuable as is this method and simple as is the technic, it yet requires not alone a training in bacteriology, but apparatus, media, etc., that must constantly be on hand and ready at all times to be brought into use. In larger cities with their medical colleges, hospitals and municipal laboratories there is comparatively little difficulty in finding the man and the appliances close at hand. But what about the "country doctor" and physicians in small towns? How can they, however much they may desire it, make their early diagnosis of typhoid or of pneumococcus bacteriemia by the blood examination? It is well-nigh impossible for the average physician in the smaller town, or in the city for that matter, even though he may possess the requisite knowledge and technical skill, to keep his private clinical laboratory up to the mark, supplied with fresh culture media and stock control cultures, or to watch and follow through carefully a bacterial growth. He must depend on assistance.

The solution of this difficulty lies in one of several directions. The busy practitioner may attach to himself a competent recent graduate who will have charge of the private clinical laboratory. Or the man who is not too busy may be able to attend to practice and to the laboratory work, too. But it will be a rare man who will do this for a long time. A more practicable plan is for several physicians in a small town, or even in adjoining towns, to unite in supporting a small clinical laboratory that shall be in charge of some suitable man, naturally, a recent graduate, but one with good laboratory and hospital training. He may be paid by salary, or in any other way that is mutually arranged. The apparatus may be his own or belong to the physicians who support the laboratory. These are details that can be settled according to local conditions. This communal rural laboratory, within telephonic call of all physicians for miles around, would be an immense help to the country physician and would have an influence that would be distinctly elevating not only on the medical profession of the neighborhood, but on the public as well. A demonstration of the practical value of applied scientific knowledge would arouse in the people an increased interest in medical matters, create a heightened respect for the physician, and bring about a more intelligent discussion of, and action on, matters of personal and public health.

By all means let us have rural laboratories, either private, communal or under the supervision of local or county medical societies. This work county societies in many places could well take up. There is no reason why the city should have a monopoly in the way of examining sputum, stomach contents or blood. There is every reason why in the smaller towns work of this sort should be done, differing from that done in the city only in quantity.

Medical News.

MARYLAND.

Baltimore.

Cocain Addiction Increasing.—Retail druggists say that the demand for cocain is increasing. One pharmacist, whose store is centrally located, is said to take in from $5 to $10 in 5 and 10 cent sales of cocain every night between 11 and 1 o'clock.

Personal.—Dr. Joshua W. Hering has declined renomination as state comptroller, which he has held for two terms.——Dr. A. C. Poole is in Paris.——Dr. Smith Hollins McKim has moved to New York.——H. Barton Jacobs is at Trouville, France.

Scarlet Fever and Diphtheria Increasing.—During the first seven months of this year there were 327 more cases of scarlet fever and 249 more cases of diphtheria than during the corresponding period of last year. The health department claims that this is due to too early release of sick children from quarantine.

Deaths of the Week.—The deaths for the week ended August 22 were 202, a rate of 18.93 per 1,000 per annum. It is notable that cancer comes second on the list of death causes. The following are the principal causes: Consumption, 28; cancer, 15; diarrhea, pneumonia and Bright's disease, each 11; heart disease, 9. Scarlet fever, typhoid fever and diphtheria are prevalent.

MASSACHUSETTS.

Glanders.—Another case of glanders contracted by the owner from his horse is reported from Methuen. It necessitated the amputation of an arm.

Not Proven.—The charge against Dr. J. M. Jones, Bay City, of failure to report a case of contagious disease to the local board of health was not proven, and the defendant was discharged.

Typhoid from Milk.—An epidemic of typhoid fever at Fall River has been traced to the contamination of milk on one route. Apparently the germs entered the milk when the farmer entirely submerged his cans full of milk in a well.

Personal.—Dr. John W. Crawford, Lawrence, is in the Massachusetts General Hospital, seriously ill from septicemia due to an operation wound.——Dr. Thomas B. Shea, Boston, has gone to Europe.——Dr. John Gallagher has been appointed physician to the House of Providence Hospital, Holyoke, vice Dr. William Powers, resigned.

Lowell Water Impure.—The score and more of typhoid fever cases reported in Lowell, Mass., since August 1, are believed to be due to contamination of the drinking water. The city gets its supply from driven wells, but after a large fire recently a check valve failed to work and river water was for a time permitted to enter the city mains.

MICHIGAN.

Personal.—Dr. Frank C. Myers, Kalamazoo, has moved to Spokane, Wash., on account of the ill health of his wife. He has purchased the practice of Dr. John R. Leadsworth.

The Most Dangerous Communicable Diseases.—Including reports by regular observers and others, meningitis was reported present in Michigan during the month of July, 1903, at 5 places; whooping cough at 40 places; diphtheria at 55 places; typhoid fever at 79 places; smallpox at 81 places; measles at

85 places; scarlet fever at 96 places, and consumption at 216 places. Reports from all sources show meningitis reported present at 2 places more; whooping cough at 3 places less; diphtheria at 13 places less; typhoid fever at 14 places more; smallpox at 26 places less; measles at 28 places less; scarlet fever at 13 places less, and consumption at 8 places more, in the month of July, 1903, than in the preceding month.

July Mortality of Michigan.—There were 2,653 deaths reported for July, or 334 more than during the preceding month. The death-rate for July was 12.6 per 1,000 per annum. There were 566 deaths of infants under 1 year, 197 deaths of children from 1 to 4 years, and 711 deaths of persons aged 65 years and over. Important causes of death were as follows: Tuberculosis, 206; typhoid fever, 27; diphtheria, 37; scarlet fever, 13; measles, 12; whooping cough, 38; pneumonia, 82; diarrhea and enteritis, under 2 years, 271; cancer, 138; accidents and violence, 274, including 58 deaths from drowning and 11 deaths from lightning. There were 2 deaths reported from smallpox during the month, and 27 deaths from lockjaw, nearly all of which were due to Fourth of July accidents, caused by the use of toy pistols.

Comparative Prevalence of Disease.—For July, 1903, compared with the preceding month, diarrhea, cholera morbus, intermittent fever, whooping cough, dysentery, cholera infantum and inflammation of brain were more prevalent; and influenza, measles, scarlet fever, pneumonia and meningitis less prevalent. For the same month, compared with the average for July in the ten years, 1893-1902, tonsillitis, scarlet fever, smallpox, diphtheria and inflammation of brain were more than usually prevalent; and neuralgia, diarrhea, consumption, influenza, cholera morbus, intermittent fever, dysentery, remittent fever, inflammation of bowels, cholera infantum, erysipelas and meningitis were less than usually prevalent. Diarrhea, dysentery, cholera infantum and cholera morbus are usually most prevalent during July, August, September and October, but these diseases were from twenty to fifty-seven per cent. less prevalent than usual in the July just passed.

MINNESOTA.

Change of Name.—The Minnesota State Medical Society has filed papers changing its name to Minnesota State Medical Association.

Fire in Medical College.—Damage amounting to about $5,000 was caused by a fire in the basement of the medical department at the state university.

Ames Asks Aid.—Former Mayor Dr. Albert A. Ames, Minneapolis, now under sentence of imprisonment for bribery, has made application for pension on account of injuries received during the Civil War.

Correction.—Dr. Robert F. Lynch, Monticello, writes asking that the error whereby his name appeared in the report of the organization of the Wright County Medical Society as "Albert F." Lynch be corrected. THE JOURNAL printed the name as "Albert F." because it is so given in Polk's Directory, which is, as a rule, correct.

Personal.—Dr. Charles A. Lapierre, Minneapolis, has been seriously ill from an infected wound of the hand.——Dr. John B. Dunn, St. Cloud, has gone to Europe.——Dr. George A. Stevenson, Albert Lea, has returned from a prolonged tour of Europe.——Dr. Charles H. Norred, Minneapolis, has been appointed surgeon to the Minnesota Soldiers' Home.

NEW JERSEY.

Smallpox in Bridgeton.—Smallpox has again appeared in Bridgeton. The treasury is empty and the city council has refused to give the board of health any more money.

Inspect Trenton Dairies.—The Board of Health of Trenton, acting in conjunction with the State Board of Health, has ordered an inspection of all the dairies of the Trenton milkmen.

Attachment Issued on Hospital.—The real and personal property of the Elizabeth General Hospital has been attached for a long-standing debt of $4,393. The hospital is valued at $100,000. Ex-Governor Foster M. Voorhees is president of the institution.

Enforcement of Child Labor Law.—Chief State Factory Inspector Wood has instructed his deputies strictly to enforce the new child labor law, which goes into effect September 13. The new law makes the employment of children under 14 a misdemeanor, punishable by a fine of $200 or imprisonment for one year.

Anthrax.—A serious epidemic of anthrax among cattle is reported in the vicinity of Lower Alloway. Thirty head were buried on Round Island in one day. The law requires their burial six feet below the surface and the use of a layer of lime. The inoculating process is used on cattle as a preventive measure. The board of health enjoins the citizens to observe the law concerning contagious diseases of cattle.

NEW YORK.

Arrests Incubator Proprietor.—An overzealous member of the New York Society for the Prevention of Cruelty to Children caused the arrest of Dr. Martin A. Cooney, proprietor of the infant incubator at Luna Park, Coney Island, for running a baby farm.

Needs Endowment.—Albany Medical College has appealed to its alumni to provide an endowment fund producing at least $5,000 a year for each department, to solve the problem of supporting the laboratories, which has become a question of paramount importance.

Personal.—Dr. Abram T. Kerr, secretary of the Cornell medical faculty, Ithaca, has been appointed health officer of Ithaca, vice Dr. Edward Hitchcock, Jr., on leave of absence.——Dr. Carl W. Walser, has been appointed assistant house physician at the Presbyterian Hospital, Manhattan.

Addition to Medical Library.—The medical library in Stimson Hall, Cornell University, Ithaca, has just received an addition in the form of the medical library of the late Dr. Charles E. Van Cleef, a graduate of Cornell, who died in 1896. This gift consists of about 250 volumes of standard medical works.

Buffalo.

Personal.—Dr. Frederick Preiss has returned after an extended tour of Europe.

Disposal of Garbage.—Commissioner Ward has signed the contract with the Buffalo Sanitary Company for collecting and disposing of the city garbage. Work will be begun September 1. The city will pay about $170,000 a year.

Currents and Water Contamination.—A dozen new floats of an improved order have been placed in the lake near Stony Point by the Health Department for the purpose of studying the effects of currents on water contamination. Mr. Fuller, the water expert from New York, is continuing his research experiments on the water supply of Buffalo.

Emergency Hospital Report.—The first annual report of the Emergency Hospital of the Sisters of Charity shows that during the year the number of patients admitted to the hospital was 1,190; of that number 1,038 were discharged and 100 died. The number of patients who were treated without fee was 330, those who paid partially were 630, and those who settled in full were 235. The total number of cases treated in the dispensary was 2,479 and the total number of old cases treated in the dispensary was 9,688. The total number of consultations was 12,167.

New York City.

Cabot Resigns.—Dr. Follen Cabot, Jr., assistant bacteriologist of the Department of Health, in charge of rabies research, resigned, August 12.

New York Eye and Ear Infirmary.—By the generosity of the late William C. Schermerhorn an ophthalmic ward was added to the hospital, and now his daughters have provided for the furnishing and surgical equipment of this portion of the hospital.

Inspectors Under Fire.—Out of ten medical inspectors of Brooklyn against whom charges were preferred, eight were found guilty. Three of these were dismissed, four were fined and one was censured. The charge in each case was that the inspector permitted houses to be disinfected before the determination of the contagious disease.

Herzog Rating Stands.—The protest of Dr. Alfred W. Herzog as regards his rating on examination has been overruled by the Municipal Civil Service Commission, which has decided that taking into consideration the ratings received by others who tried the examination, there was nothing remarkable in the rating that had been given to him.

Work Lags on Woman's Hospital.—For some time past the work at the Woman's Hospital has been at a standstill save for the use of a very small temporary pavilion. It is expected, however, that work will be begun very soon on the new edifice, which is to be six stories in height, with lecture hall, chapel, private and ordinary wards and a new and thoroughly modern equipment, and which is expected to cost $610,000.

PENNSYLVANIA.

Rabies.—Two persons at West Chester and ten children at Punxsutawney are said to have been bitten by dogs proved by postmortem examination to have been affected by rabies.

Typhoid in Pittsburg.—Between July 1 and August 8 300 cases of typhoid fever were reported to the Pittsburg Board of Health, with 52 deaths, a death rate of 17.33 per cent. On August 10, 17 new cases were reported.

Oleomargarin for Poorhouse Inmates.—In the case of the Commonwealth against the County Commissioners and other officials of the Jefferson County poorhouse at Brookville on the charge of furnishing the inmates of the institution oleomargarin instead of butter, the defendants admitted the charge. The defense raises two questions to be settled by the court: First, the oleomargarin law is unconstitutional; second, a county poorhouse is not such a charitable institution as is contemplated by the law. A penalty of $1,000 fine or two years' imprisonment, or both, is provided for violation of the law.

Philadelphia.

Toy Pistol Prosecutions.—District Attorney Bell has begun prosecution of dealers who are charged with having sold toy pistols to minors. Several dealers, at a recent preliminary hearing, entered bail to answer at court. It is said to be the purpose of the prosecution to bring the cases to trial at an early date.

Isolation Hospital Nearly Under Roof.—The mayor and other city officials recently visited the Macalester farm, the site for the projected new municipal hospital. Sites for the buildings and plans for beautifying the grounds were approved. The one-story structure for the smallpox department with accommodations for about 200 patients, is nearly under roof, and is expected to be ready for the reception of patients next winter.

Impure Beer.—Several retail liquor dealers and bottlers have recently been arraigned before a magistrate charged by Dairy and Food Commissioner Warren with selling adulterated beer. The affidavits allege that the samples of beer analyzed contained salicylic acid. It is the avowed purpose to strike at the manufacturer of impure products, and it is probable that the retailers will simply be held as witnesses against the brewers.

To Succeed Welch.—Dr. B. Franklin Royer, chief resident physician of the Jefferson Medical College Hospital, has been appointed chief resident physician of the Municipal Hospital, and will begin his new duties September 1. Dr. William M. Welch, who for twenty-five years has been physician-in-charge of the Municipal Hospital, is made consulting physician to the institution. The office of chief resident physician is a new one, and city councils will be asked to create the position by ordinance.

The Ball-Park Catastrophe.—By the crowding of a balcony overhanging the street at the Philadelphia Ball Park on August 8, several hundred people were precipitated to the pavement. Many were very seriously injured, and ten deaths or more resulted. Several of the up-town hospitals were taxed to their utmost to care for the victims. The coroner and other city officials are taking great pains to fix the responsibility for the accident. It is claimed that timbers originally strong had become rotten through exposure for several years, but the whole matter remains to be settled by official investigation.

GENERAL.

Plague in Peru.—Bubonic plague has caused 24 cases and 15 deaths at Pacasmayo, Peru.

Yellow Fever in Mexico.—Alarm has been felt along the Texas border over the occurrence of several cases of yellow fever in Mexico. Quarantine was established against a few cities, but no serious outbreak has occurred.

Great Britain to Check Immigration.—The royal commission on alien immigration recommends regulations similar in many respects to those of the United States. No educational qualification is proposed. Provision is made for deportation at the expense of the ship company that brought the immigrant in case of proof of his undesirability during two years after arrival.

FOREIGN.

Personal.—Dr. Peter Martin Keller, Huntley, New Zealand, has been appointed surgeon-captain in the New Zealand volunteer medical staff.

Sixtieth Professional Anniversary.—The Nestor of German alienists, Dr. Lachr of Zehlendorf near Berlin, has recently celebrated the sixtieth anniversary of his entering on the practice of medicine. He was born in 1820, and was one of the founders of the German Psychiatric Society.

Von Leyden's Jubilee.—Prof. E. von Leyden of Berlin entered on his professional career, August 11, fifty years ago, and the anniversary was celebrated by his friends with much ceremony this year. The Berlin University, as is customary, renewed his diploma "with honor," and also those of Drs. A. Hildebrandt, L. Rosenthal and F. Polland, who graduated with him.

Charlatan Ads in the Berlin Papers.—Some time ago we announced that the publisher of three prominent daily papers in Berlin had applied to the local medical association for expert opinion on the medical ads in his papers, stating that he wished to accept only those that met the approval of the profession. The medical society complied with his request with pleased alacrity, but the charlatan ads are beginning to appear once more in his papers, as our German exchanges note in sorrow—possibly the medical experts are away on their vacation, one sarcastically suggests.

Scarcity of Hospital Accommodations at Moscow.—The city of Moscow has numerous hospitals and money has been lavishly given by philanthropic capitalists for model medical schools and clinics. It is with some surprise that we read that in June 1,457 sick persons were turned away from the city hospitals and 207 from the others on account of lack of accommodations. July 1 the total number of patients in the city hospitals was 4,722, and in the others 1,020. As the number of the insane is constantly increasing and the present institutions are already overcrowded, the municipal authorities have recently made arrangements to place the quiet insane patients in private houses.

Scientific Devotion of Roux and Metchnikoff.—Roux and Metchnikoff have succeeded, they believe, in inoculating a chimpanzee with syphilis. It is accepted as such by Fournier, although he remarks that the appearance of secondary symptoms would be still more conclusive. The researches are to be continued, and as the Institut Pasteur, with which these scientists are connected, is not rich enough to supply the necessary material in the line of chimpanzees and other monkeys required for the purpose, Roux and Metchnikoff propose to devote to it the prizes recently bestowed on them. As our readers will remember, Roux received the Osiris $20,000 prize and Metchnikoff a $1,000 prize from the Institute.

The Preventive Circular.—THE JOURNAL has mentioned the German "warning circular" to be distributed by physicians among their patients. It is written by Professors Erb, C. Fränkel and Jadassohn and the text is published in full in the *Allg. Med. Ct.-Ztg.* for August 8, 1903. It contains nine paragraphs, the whole about as long as a column and a half of THE JOURNAL. It states: 1, that sexual abstinence is not injurious to health as a rule; 2, describes the symptoms and contagiousness of gonorrhea and syphilis and their consequences; 3, warns against promiscuous intercourse, and that women may be capable of transmitting the disease without being aware of their infected condition; 4, warns that the most insignificant wound or lesion on the genitals may be the entering point for infection, and should be submitted at once to the examination of some qualified physician, avoiding quacks, nature healers, etc. "The danger of venereal diseases, which is frequently under-estimated and frequently over-estimated, may be materially diminished by appropriate medical assistance. Nearly every case can be completely cured, although a long time may elapse before this can be accomplished." 5. The subject himself is unable to tell when he is cured, and the qualified physician has to examine him again and again through months and years in order to follow the course of the disease and apply treatment at the proper moment. In a separate paragraph the subject is warned that he must not allow himself to be deterred from mercurial treatment by the ads of charlatans. "The general opinion of the medical profession is that it is necessary, extraordinarily effective, and can never do harm in the hands of a trained physician." "He who suspends treatment without the advice of a physician, has only himself to blame if symptoms recur, which may not be until after a long interval. Such neglect is not only liable to injure himself, but may be the means of injuring others." The German code is then cited to show that a penalty of three years' imprisonment or $250 fine may be imposed for personal injury or injury to health, while the penalty is much more severe if the loss of an eye or other important member results from the injury. The danger of infecting others during the stage of incubation is

also emphasized, and the subject is warned always to inform his medical attendants later that he has had a venereal disease. In conclusion the circular cautions that there are no absolutely reliable protecting measures against venereal infection, but at the same time advises the use of some such measure, in regard to which the physician is alone competent to pass judgment. The danger of infection while under the influence of alcohol is commented on, and the extragenital sources of infection. Intimate contact with unknown persons or common use of pipes, razors, dishes, etc., is warned against, and fondling children whose medical antecedents are unknown. All persons with a venereal disease are cautioned in regard to the hygienic measures to prevent extragenital infection of others, as they may spread the disease by lack of care in this respect. These circulars are to be distributed to all physicians of Germany through the mediation of the county and local medical associations or the officials of the sickness insurance societies.

Correspondence.

Notes from Manchester and London.

London, July, 1903.

To the Editor:—Mr. George A. Wright, well known through his excellent work on early excision of the hip, is still active at the Royal Infirmary, Manchester, where the writer found him at work in the operating room. His first case was one of infraorbital neuralgia, which he treated by exposing the nerve and injecting into it a 2 per cent. solution of osmic acid; the results of this method, which does not abolish nerve function, are said to be very gratifying. In a case of extensive sinuses of the ilium, the opening was enlarged, and the sinus curetted and flushed out with turpentine, an application of which Mr. Wright thinks very highly. It is not painful, and does not interfere with primary union. The third operation was the opening of a pulmonary abscess in a young child.

In conversation Mr. Wright said he was treating young children with congenital clubfoot with appropriate tarsectomies, and the double cases with astragalectomy. In tuberculous knees erosion, through a transverse incision dividing the patella, is the favorite treatment. The patella is afterward stitched with silk. Hip cases are treated at first with the Thomas splint, but if after ten or twelve months they have not done well the joint is excised. Mr. Wright does not favor the manual replacement of congenitally dislocated hips on the ground that the acetabulum is usually too defective to assure a permanent result.

Although Mr. Wright has resigned his connection with the Children's Hospital at Pendlebury, about four miles from Manchester, he very kindly gave me a card to the house surgeon, who was most courteous. The Pendlebury Hospital is modern, and is built in separate wards, one story high, connected by roomy corridors, and with ample space between. Thus light and ventilation are abundantly provided, and the children are easily moved on mattresses into the open air. Each ward has 26 beds, and two separate beds for the isolation of contagious diseases. The treatment of hip, knee and talipes cases was much practiced by Mr. Wright. Of two cases of laminectomy for Pott's paraplegia one had improved considerably, the other only as to control of sphincters. One case of double luxation of the hip was in a frame holding the thighs abducted, but although it was four months after the operaton, the patient was still in bed. Knockknees are corrected after supracondylar division of the femur with the Adams saw, but plaster is not applied until a week or ten days later. Tendon grafting for paralytic deformities was frequently practiced.

On reaching London the writer found but little activity at the Royal Orthopedic and National Orthopedic hospitals, as it was the dull season. Each has about 60 beds and a large out-patient service; it is gratifying to learn that there is a good prospect for the consolidation of the two institutions, and for the erection of a large, modern hospital. Some of the surgeons connected with these institutions are very conservative, confining their operative work to tenotomies and bloodless manipulations.

It was, however, the writer's privilege to see Mr. E. M. Little correct a paralytic varus with the Thomas wrench, and also do an improved Phelps operation in another case. The modification consisted in making a v-shaped incision, with the base at the outer border of the sole, enabling the operator to cover over the deep wound.

Of all the London surgeons the writer was most anxious to see Mr. Bernard Roth, who is, perhaps, the foremost representativeof the Purdy gymnastic treatment of lateral curvature of the spine. Mr. Roth demonstrated his work in London, and very kindly invited the writer to accompany him to Brighton, about an hour's run, where he also has a large class. The patients ranged in age from early childhood to advanced life; all were treated by exercises alone, and each in turn passed under the hands of Mr. Roth, who was at all times the center of inspiration. The system is peculiar, as the work is entirely individual, and yet many patients are handled in a short space of time. The exercises, mainly resistive flexion, extension, and rotation of the trunk, and horizontal exercises for trunk and legs are extremely simple, but so planned as to develop the weakened muscles very rapidly. Mr. Roth's practice is to give symmetrical exercises daily for a month, then to ascertain the "key-note" position and to include exercises in this position for two months longer; after this the patient practices certain exercises at home, reporting at long intervals; no supports are used. Careful notes and patterns are taken of each patient, so that progress can be tested. Mr. Roth, like Mr. Jones and other eminent authorities, freely admits that the rotation is incurable, but pain, which he finds in the majority of cases, is relieved, health and vigor imparted, the progress of the affection checked, and in favorable cases the posture improved. With the help of several assistants, Mr. Roth is able to treat some thirty cases in about two hours. Between each set of exercises, the patients rest on benches at the sides of the room; they seem to heartily enjoy the work, a point which Mr. Roth considers essential to success. The strength developed in a short time in the muscles of the back and waist is surprising, but far more wonderful are the energy and skill which Mr. Roth puts into his work, his general control of the class, and the directness of his methods. Practically the only apparatus used are the vertical ladder, the high bench, and the padded bar, but with his hands and these simple appliances Mr. Roth obtains speedy and enviable results.

Henry Ling Taylor.

(New York address, 125 W. 58th Street.)

The Alleged Cure for Lockjaw.

Chicago, Aug. 25, 1903.

To the Editor:—Certain publicity given by the lay press to a case of tetanus recently treated by me, and an editorial in The Journal last week, make the following statement necessary:

In the first place, I disclaim any pretention to the discovery of a specific cure for tetanus or for any other disease. However, during the past year I have made a study of the diuretic effects of certain salt solutions when injected directly into the circulation in mammals (rabbits), and the power of such diuretic saline solutions to eliminate soluble toxins from the body. To prove the theory I chose tetanus toxin, which I found could be eliminated from the body, at least in part, after sufficient time had elapsed for it to set up its characteristic symptoms. I tested this on a number of animals (each animal being controlled) with a large per cent. of positive results.

In the case of tetanus in question I simply carried over my animal experiments to a human being, and in this particular case with positive results. The case was a boy, 11 years old, who had sustained a lacerated wound of the foot. Eight days after the injury tetanus began to develop. The symptoms did not progress very rapidly. I was called to see the boy nine days after the first appearance of the disease, and while the symptoms were pronounced, all the voluntary muscles being in a state of tetanus, I gave the opinion that the disease would probably assume a chronic character. At any rate, I consid-

ered the patient had about as good a chance to recover without as with the intervention of physicians. Four days afterward (the thirteenth day of the disease) I was called again, and found the boy manifesting alarming symptoms of acute tetanus. His whole voluntary muscular system was in a complete tetanus and convulsions were following each other in rapid succession. Pulse 150 and temperature 105. Bowels had been moving involuntarily. In two and a half hours I injected into the circulation 600 c.c. of a solution containing NaCl, Na_2SO_4, $Na_3C_6H_5O_7$, and $CaCl_2$ in the proportions given below. During the injection the pulse fell to 104 and remained so until the following afternoon, when the pulse began to increase and soon reached 140, and convulsions began to threaten the life of the patient again. The treatment was repeated with a like good result, the pulse this time reaching 98. A large excretion of urine followed. The next day the pulse went up to 130, and the treatment was repeated, when the pulse fell to 94 and the temperature to 100 (per rectum). No further treatment seemed necessary, and the boy has steadily improved ever since, now the tenth day after the last treatment.

When I began the treatment the symptoms indicated a fatal termination, and that before many hours, but as I have had opportunity to see at least one case recover from seemingly an acute infection without any treatment at all I must refrain from drawing any conclusions from this case.

Further, let me say, such a treatment of disease partakes of none of the elements of the specific antitoxin treatment of disease. It is simply a cell stimulant, combined with diuresis. I can say, at least, it is a safe treatment and if carried out slowly is certainly beneficial, but not a specific.

The following is the solution:

M/8 NaCl	500 c.c.
M/8 $Na_2SO_4+10H_2O$	250 c.c.
M/24 $Na_3C_6H_5O_7+5\frac{1}{2}H_2O$	245 c.c.
M/8 $CaCl_2+6H_2O$	5 c.c.
	1000 c.c.

This being interpreted gives the following:

℞. Sodii chlorid	7	3125
Sodii sulph	10	06+
Sodii citrat	3	364+
Calcii chlorid	0	136+
Aquæ	1000	00

To get the best effects the injection should proceed very slowly, not more than 3 c.c. per minute.

While as yet nothing is claimed for the treatment, I hope before long to be in possession of sufficient clinical data to either prove or disprove its efficiency, and until such a test is made and published in a *professional* manner, no confidence is to be placed in the treatment. S. A. MATTHEWS, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

NAUHEIM BATHS.

MANSFIELD, LA., Aug. 3, 1903.

To the Editor:—Please let me know the composition, mode of application and indications for the artificial Nauheim baths in chronic heart disease. H. J. PARSONS.

ANS.—The composition of the Nauheim baths is largely chlorid of sodium and chlorid of calcium, at least they are the more active constituents. There are a number of springs that are utilized and the baths are also given artificially to some extent. Bezley Thorne says that the Schott brothers have insisted that similar, if not identical, effects can be obtained from artificial baths, prepared to imitate the Nauheim waters in their principal mineral ingredients. "Thus it is recommended that the treatment should commence with a 1 per cent. solution of chlorid of sodium, and that the strength should be gradually raised to 2 or 3 per cent. For increasing the cutaneous excitation, chlorid of calcium is the salt to be relied on. The initial strength of the bath, with regard to that ingredient, should be 0.2 per cent., approximately that of No. 7 spring, and, by increasing additions, it may be raised to 0.3 per cent., that is, to about the strength of No. 12 spring, and eventually to 0.5 per cent. Such varying degrees of concentration may be obtained by the proportional use of the crystallized Nauheim bath salt, of the mother-lye or of calcium chlorid, and of Mediterranean sea residue, which also contains chlorid of sodium and of calcium in the proportions necessary for the preparations of initial baths, together with traces of bromids and iodids.

"For the production of carbonic acid effervescence the action of hydrochloric acid on bicarbonate of soda may be relied on. As a state of chemical purity is not required by the circumstances of the case, the articles of commerce are sufficient for the purpose. Two ways of employing the reagents are suggested, the one calculated to induce slow and gradual, the other rapid and almost immediate effervescence. In the case of the first, the various salts, including the requisite proportion of bicarbonate of soda, having been dissolved, a bottle containing the acid is laid at the bottom of the bath and, the stopper having been withdrawn, it is moved about from time to time. The bath will be ready for use in two or three hours. For the more rapid production of effervescence the stopper of the bottle containing the acid is loosened but retained in position, the bottle having then been inverted and lowered until its mouth is just below the surface of the water, the stopper is withdrawn and the bottle is moved about so as to diffuse a layer of acid as uniformly as possible over the surface of the bath. By this means the bath will be prepared in about five minutes. It will be useful to employ baths of three degrees of effervescence:

Mild—½ lb. $NaHCO_3$ to ¾ lb. HCl (25 per cent.).
Medium—1 lb. $NaHCO_3$ to 1½ lbs. HCl.
Strong (Sprudel strength)—2 lbs. $NaHCO_3$ to 3 lbs. HCl.

"Except in the case of porcelain baths it is desirable to ensure a slight excess of alkali in order to prevent corrosion."

The indications are, in general, feeble heart action and circulation, lack of vasomotor tone, dilatation. Consult a good work on therapeutics.

DUTY OF PHYSICIAN IN EMERGENCY CASE.

MINNESOTA, Aug. 22, 1903.

To the Editor:—A few days ago a friend of the writer was hurt in a gasolene launch at a lake resort, three miles from town. The injury consisted in a flesh wound in the upper part of leg, five or six inches long. The writer, being the family physician, was telephoned for, but, due to unavoidable detention, could not get there for three-quarters of an hour. On the arrival of the writer he found that another physician, who is on his vacation and who lives in St. Louis, had been called in, as he was living in the next house. This physician had shaved the leg and put on an antiseptic cotton dressing, but, having no instruments, he had to await my arrival. When I arrived, bringing the necessary instruments, bandages, etc., the emergency physician, without any explanation, helped himself to the instruments and proceeded to sew up the wound. This he did without protest from me, as I thought it best not to raise any trouble at the time. An explanation between the two physicians happened later; the St. Louis physician maintaining that, inasmuch as he had started the work, he had a right to help himself to the other physician's instruments and finish; the family physician, however, claims that, inasmuch as the physician was from St. Louis and outside his jurisdiction, had no instruments, and as he had done all he could, he should immediately have withdrawn from the case, leaving it to the family physician to finish. Who is right? L. G.

ANS.—The Principles of Medical Ethics, Article iv, Section 6, is explicit: "When a physician is called to an urgent case, because the family attendant is not at hand, unless assistance in consultation is desired, the former should resign the care of the patient immediately on the arrival of the family physician."

WHOLLY SMOKE.

Dr. C. J. Gose, Kinderhook, Ill., sends us the following, with the instruction, if it is not fit for publication, to convert it into smoke:

I've heard of lies, great big lies,
And told a few myself,
But of all the lies I ever heard,
This knocks me off the shelf.

A doctor man once told me this,
(And I thought him very fractious),
"In my time I've been behind
Three weeks in my practice."

EXCLUSION OF PHYSICIAN'S OFFICE FROM RESIDENCE DISTRICT.

ST. LOUIS, Aug. 21, 1903.

To the Editor:—Has the attempt ever been made to apply the restrictions which apply to a trade or business against a physician desiring to regularly practice the learned profession of medicine in a restricted residence district? W. D.

ANS.—Do you mean to ask: Can a physician be prevented from opening an office anywhere he wishes to? Leaving out of account saloons, gambling houses or other businesses that may be decided to be nuisances (for example, a rendering plant), we know of no *legal restriction* that can exclude a business shop from any district, except the *agreement* in lease or deed or otherwise that property is not to be used for certain specified purposes. Since the owner

of property is not a servant of the public, he may refuse to sell or lease to undesirable persons. This has excluded physicians because they were going to open offices, which action was undesired by lessors.

MENTAL STATUS IN PHTHISIS—INFORMATION WANTED.

OKLAHOMA CITY, O. T., Aug. 21, 1903.

To the Editor:—Recognizing THE JOURNAL of the American Medical Association as the principal organ of leading physicians of America, and desiring more authority on the following subject, I wish to ask two simple questions, and will thank in advance as many readers as will kindly state their own experience and cite such authorities as they may have read on the subject, giving chapter and page: 1. Are persons who are afflicted with pulmonary consumption prone to attribute their physical weakness to some other cause than consumption? 2. Are persons so afflicted more easily turned against their dearest friends by designing people than when in a normal state of health? J. L. SHORT.

Marriages.

HERBERT E. MARKWORT, M.D., to Miss Helen Husemeyer, both of St. Louis, August 8.

JOHN JACOB WUERTH, M.D., to Miss Georgia Marion Pitkin, both of Chicago, August 18.

CHARLES D. SHELTON, M.D., to Miss Jessie Ferguson, both of Bloomfield, Iowa, August 5.

ABRAHAM GIVEN SHORTLE, M.D., to Miss Alice Stanley Mitchell, both of Chicago, August 18.

NELSON MERRILL, M.D., Marshalltown, Iowa, to Miss Flora Belle McMahon of Cissna Park, Ill., August 5.

EDWIN A. DAVIS, M.D., Mammoth, W. Va., to Miss May Langhorne Johnson of St. Louis, at Hardine, near Elkins, W. Va., August 6.

Deaths.

George D. Cross, M.D. University of Pennsylvania, Philadelphia, 1889, a leading ophthalmologist of Pennsylvania, assistant surgeon Wills Eye Hospital, and ophthalmologist St. Clement's Hospital, Philadelphia, a member of the American Medical Association, Delaware County Medical Society, Philadelphia Medical Society and the Medical Society of the State of Pennsylvania, died at his home in Chester, Pa., August 8, after an illness of eighteen months, aged 51.

Patrick Carter Lodge, M.D. University of Vermont, Burlington, 1899, whose name was dropped from the roll of the Waterbury (Conn.) Medical Association, after an acrimonious discussion regarding the nature and treatment of smallpox, shot himself in the head, at Waterbury, August 5, and died a few hours later, aged nearly 60.

Francis Marion Powell, M.D. Starling Medical College, Columbus, Ohio, 1875, for more than twenty years superintendent of the Iowa Institution for Feeble-Minded Children, Glenwood, a member of the Iowa State Medical Society, died at Mercy Hospital, Chicago, August 16, after an operation for gallstones, aged 55.

Josiah D. Cotton, M.D. University of Louisville, Ky., 1847, surgeon of the Ninety-Second Ohio Volunteer Infantry in the Civil War, a member of the American Medical Association, and one of the oldest members of the Ohio State Medical Society, died at his home in Marietta, Ohio, August 6, after a short illness, aged 81.

Clarence John Garitee, M.D. University of Pennsylvania, Philadelphia, 1894, an active member of the Philadelphia Pathological Society, Philadelphia Pediatric Society and Philadelphia County Medical Society, died at his home in Philadelphia, August 10, from heart disease, following septicemia, aged 31.

Samuel Bryant Potter, M.D. Jefferson Medical College, Philadelphia, 1854, a member of the American Medical Association, and for several years vice-president of the North Central Ohio Medical Society, died at his home in Fredericktown, Ohio, August 5, from stricture of the bowel, aged 74.

George W. Rolerfort, M.D. Leonard Medical School, Raleigh, N. C., 1889, a member of the American Medical Association, Medical Society of the State of New Jersey, and Essex County Medical Society, died suddenly from apoplexy at his home in Newark, August 6, aged 43.

L. W. Bacon, M.D. Medical School of Maine, Bowdoin College, Brunswick, who retired from practice at Portage, Wis., in 1887, died at the home of his daughters in Minneapolis, August 14, from heart disease, aged 96.

Charles W. Piper, M.D. University of Michigan, Ann Arbor, 1884, of Wurtsboro, N. Y., a member of the New York State Medical Association, died at the New York Hospital from septicemia due to an autopsy wound, August 10, aged 46.

Joseph Muir Corbett, M.B., Ch.B., Glasgow, 1897, surgeon of the Anchor Line steamer *Astoria*, was drowned in the Hudson River, and his body was found August 7. His death is believed to have been accidental.

Burwell G. Abernathy, M.D. College of Physicians and Surgeons, Baltimore, 1880, one of the organizers of the Jefferson County (Ala.) Medical Society, died at his home in Tampa, Fla., July 30, after a long illness.

George Johnston, M.D. Jefferson Medical College, Philadelphia, who retired from active practice about ten years ago, died at his home in Connellsville, Pa., August 9, aged 84.

Moses Bruckheimer, M.D. National Medical College, Washington, D. C., 1868, died at his home in Washington, D. C., August 7, after a short illness, aged 63.

Robert Morrison Rhea, M.D. Jefferson Medical College, Philadelphia, 1868, died at his home in Knoxville, Tenn., from acute gastritis, August 11, aged 60.

T. J. I. Pattillo, M.D., of Lee County, Ga., died at the home of his son in Macon, August 6, aged 71.

Miscellany.

Microbes Suggested in the Year 1726.—Dr. John Knott, Dublin, Ireland, writing in appreciation of "Medical Discoveries by the Non-Medical," which appeared in THE JOURNAL, May 30, 1903, says he ventures "to hope that it may interest some medical readers in the glorious land of freedom which has so long proved the refuge of the Irish race, to peruse some remarks—published in Dublin in 1726—sixty-two years before Samuel Foote's play appeared. The writer was (afterward Sir) Edward Barry, M.D. The following quotation forms the concluding paper of this author's work: 'A Treatise on a Consumption of the Lungs':"

Thus I have endeavored after the most plain, and rational manner, to account for the various Origine, and Progress of this Distemper, through its different Stages: And without forming any deceiving *Hypothesis*, have shewn how a Collection of *purulent Matter* in the *Lungs*, can only proceed from *previous Obstructions* of the *Vessels*, or a *Solution* of their *Continuity:* There is no Disease perhaps which rightly to explain, requires a more universal Knowledge of the *Animal Oeconomy;* and which hitherto has been described after a more imperfect, confused Manner. In this *Treatise* I have proposed rather to lay down a right Account of this *Distemper*, than to examine the errors of others: But, however, I cannot well avoid mentioning the Author of a late *Hypothesis* which some may be more inclined to believe, since no less than *ocular Demonstration* is offered to confirm the truth of it. This Person takes Notice, that *Ulcers* in the *Lungs* when narrowly viewed with *Microscopes*, are covered with several *Insects*, and from thence concludes that they take their first Origine from such *Animalculcs*, which being inspired with the Air, fix their Situation on the *Lungs*, and erode and ulcerate the *Vessels:* And from the same Irregular Way of Reasoning, these *Animalculcs* have been by others supposed the Cause of several Distempers, and particularly such as are *contagious:* But these Appearances may be easily accounted for, as the unavoidable Effects, not the Causes of these Diseases: For it is certain, that there is almost an infinite Number and Variety of such *Animalculcs* perpetually floating in the Air, whose chief Business consists in searching out a Place where they may find Nourishment, and a proper Situation for themselves and their young: But every living Part of a human Body has a perpetual Pulsation, which tho' imperceptible to our Eyes, is sufficiently strong to give the most uneasy Motion to those *Animalculcs* so minutely small; and entirely prevent them from fixing there for any time: But as there is no Circulation in any part that is ulcerated, the Inconvenience of this Pulsation immediately ceases, and the *purulent Matter* sends forth perpetual Steams, fit to nourish them: and by being viscid and adhesive, makes their *Nidus* so secure, that the Motion of the *Vessels* under the ulcerated Part is not strong enough to dislodge them. After the same Manner, the Blasts of Trees and Plants, may be more rationally accounted for, than by bringing small *Animalculcs* and their Eggs so many hundred Leagues to produce these Alterations. For there is a Circulation of *Humours* through every Part of Plants, and Trees, and in their aerial Tubes a more remarkable Pulsation, which is sufficiently strong to prevent these *Animalculcs* (perhaps more minute than such as are observed on *Animal Bodies*) from having a fixed and safe Situation there. But whenever any particular Wind, or Alteration of the Air, by either giving a sudden contraction to their *tender Vessels*, or a *Viscidity* to their *Juices*, produces a *Stagnation*, and thence a *Gangrene*, either in any particular Part, or in the whole, such *Animalculcs* will quickly secure this quiet State, and Nourishment.

State Boards of Registration.

Tennessee Report.—Dr. T. J. Happel, secretary of the State Board of Medical Examiners of Tennessee, reports the written examination held at Memphis, Nashville and Knoxville, March 30 and 31, 1903. (The examinations are held in the three divisions of the state on the same days. The board meets as soon as convenient and passes on the papers.) The number of subjects examined in was 8; total number of questions, 64; percentage required to pass, 75; the total number examined was 150, of whom 88 were graduates; the number passed was 120, of whom 78 were graduates. This shows that 32 per cent. of the non-graduates failed, while only 11 per cent. of the graduates failed. The graduates are listed below.

Medical Organization.

MEDICAL ORGANIZATION METHODS AND BENEFITS.

J. N. M'CORMACK, M.D.

In the report of the Committee on Organization made to the American Medical Association at the St. Paul Session in 1901, and in the valuable paper by Dr. Simmons along the same lines later, particular attention was devoted to the unorganized and almost chaotic condition of the profession of this country as a whole, in spite of the existence of so many national, semi-national and state societies of more or less excellence, to the evils resulting and inseparable therefrom, and to the urgent necessity of a uniform, systematic and universal reorganization as the only possible remedy for these conditions.

That the importance of all this was realized, and that the profession was at last ready and ripe for reform was shown by the prompt and unanimous acceptance of the entire plan of reorganization proposed for the Association itself, and the continuance of the committee with instructions to prepare uniform constitutions and by-laws to be recommended for adoption by all state and county societies. This was still more forcibly shown by the adoption of these in thirty-one states within fifteen months after they were promulgated at the Saratoga meeting, while in several states favorable reports from committees appointed to consider the subject only await the annual meetings of their respective state societies to ensure their adoption. It seems now only a question of time until every state in the Union will have accepted them, and be using the same methods to secure the same results.

If this were all, the bare statement of the foregoing facts would indicate a degree of widespread interest and activity in the medical profession of this country without a parallel in its history. But this is not all. Within all of the states which reorganized in 1902 the acceptance of the new plan was systematically followed up by the organization of county societies, and an increase in total membership and interest quite as remarkable. This interest and enthusiasm was so great that not only the councilors and other officers especially selected for the purpose took up the work with commendable zeal, but that volunteer efforts in the same direction were and are being effectively made by many others who caught the infection.

PERMANENCE.

As a natural result of this general awakening, requests have come from more thoughtful workers of every quarter for information as to how these efforts and this enthusiasm may be so intelligently directed as to make certain that the reform so auspiciously begun may be made both thorough and permanent. It is feared by many that the rapid growth of the movement, and the zeal and enthusiasm responsible for this, may themselves become sources of danger, because of the reaction and apathy likely to follow. A very proper fear is also expressed that the impression will go out that the reform will be complete and the work over as soon as all the states have accepted the new plan, and societies have been organized in every county, and especially that the latter will be left to languish and die as soon as the first sentiment which created them subsides. In the light of history, as well as in the very nature of the problems involved, these fears are well grounded and are entitled to the most careful consideration.

PROVISION AGAINST DANGERS.

That the Association fully appreciated all of these dangers in advance, and made every possible provision against them will be readily shown by such a study of the various constitutions and by-laws of the entire system, from the county societies up to the American Medical Association, as every one should give them who desires to take an intelligent part in this work. In fact, it will be found that under the new order of things one of the chief functions of the higher organizations, within their respective spheres, is to organize, maintain and form a bond of union between the county societies. One of their principal uses and powers will be, through the well-devised delegate system, to collect and concentrate the influence

and represent the opinion of a united profession, as developed and expressed in the county societies, on all the great questions relating to the educational and scientific advancement of the profession itself, or for the protection and promotion of the public health interests of the whole people. Through the same system they may be made equally efficient in radiating and diffusing the spirit of scientific investigation, and the generous emulation and mutual respect and forbearance engendered by the contact of the most advanced and liberal members gathered at the annual meetings, back through the system of delegates and organizations to the most remote society. Through such action and reaction of enlightening and ennobling influences, and the systematic supervision provided through the councilors for every county in every state, aided by THE JOURNAL of the Association and the journals or bulletins in each state, sent free to all members, all possible safeguards are made for the permanency and efficiency of these organizations in theory. With such incentives, instruction and machinery, each state association must deal with the problem within its own jurisdiction on the broad yet painstaking lines which will now be considered.

ESSENTIAL FEATURES IN STATE WORK.

While provision is made for councilor district societies and other details which may grow in importance in the future, there are five essential features in the plan on which both the immediate success and the permanency of the work of each state association depends. Named in the order of their importance they are: 1. The county society, as the unit of organization, and the foundation of, and the door to, everything above it. 2. A council, selected from the profession at large, to represent and act for the Association under well-defined restrictions in the interval of the annual meetings, and whose individual members are charged with the organization, supervision and well-being of the county societies within their respective jurisdictions. 3. A house of delegates, composed of a limited number of specially selected representatives from the county societies, as the business body of the association. To it is committed the duty of fostering in every legitimate way the scientific, legislative and material interests of the profession at the annual meetings. 4. The general meeting, made up of all the members of all the county societies who will attend, which can devote its entire time and attention to the reading and discussion of papers, and reports of scientific research and investigation. 5. A card index register for each county, and for the state, showing at a glance the status and antecedents of each physician of the jurisdiction, reputable and disreputable, including his name and address, and furnishing reliable information as a basis for an official medical directory for each state, by counties, and for the United States. To this list there should probably be added a bulletin or journal published under the auspices of the association, and sent free to all members, as a means of constant communication between the county societies, and between them and the councilors and other officials, as well as for the early publication and wide distribution of the transactions.

COUNTY SOCIETIES.

All of these features or departments are so interdependent as to be essential to the complete and permanent organization contemplated, but it will be perceived at once that the county society is made the bed-rock on which the entire superstructure rests; that it is made the chief function of the individual councilors, provided for every district in every state, to see that these are organized for and kept alive to the best interests of the members composing them, and of the profession as a whole, that the influence of every officer and agency in the entire system is focused on and directed to the same end, and that all these are to be continued until every physician of every county in every state, who can be made worthy of it, is brought under the educational and elevating influence of some county medical society. Such an organization of the profession as this is ideal, but is believed to be entirely possible, if this possibility and the necessity for it is once fully appreciated by the controlling influences in each state.

WHY SO DIFFICULT TO MAINTAIN.

For obvious reasons it has always been easy to induce leading men from widely separated sections to attend and keep up the interest in the national, the state, and even in the district medical societies, but the problems to be faced in making the frequent meetings of local or county organizations, composed of those who have, or at least think they have, competing personal and professional interests, sufficiently interesting and harmonious to secure the requisite attendance, month after month and year after year, are far different. In reality all their interests are mutual. In the best and broadest sense what benefits or hurts one benefits or hurts all. To convince them that this is true is the problem now before the profession. It has been done to a degree in a few states, and in some counties in all the states, and after a large experience the writer feels assured that it is possible everywhere. "What men have done other men can do." The difficulties are on the surface and will disappear in the face of a full recognition of their nature, and of a kind but frank and unsparing discussion.

TROUBLES OF LOCAL ORIGIN.

Widespread as are these difficulties, extending from ocean to ocean, and baneful as have been their effects on every interest of the profession, when reduced to the last analysis it will be found that all of them, large and small, in city or country, are directly traceable to rivalry and jealousy between local doctors who are in each other's way or between competing schools in the same city. A clear understanding of the truth of this proposition is essential to the purpose now in hand. Physicians are the most agreeable men in every community except in their relations with their rivals. They are often like Damon and Pythias with those from a distant city or community, while barely on speaking terms with equally good physicians of their own town or neighborhood. As these conditions largely create and emphasize the necessity for universal local organization, and at the same time, paradoxical as it may appear, constitute the chief obstacle to its accomplishment, they are entitled to a detailed consideration not hitherto accorded them.

RESPONSIBILITY OF MEDICAL COLLEGES.

If we will consider the influence these conditions exert continuously on a young man taking up the study of medicine, from his entrance in school up to his graduation, follow him through his early experience as a practitioner, and then make the application general, we fairly epitomize evils as widely prevalent as they are deplorable. Matriculating in one of our average low-grade schools, three, four or five in a city where there is only room or need for one, all probably without endowment, and run as private commercial enterprises, with the fierce struggle for patronage and existence inseparable from such conditions, he is surrounded more or less constantly throughout his college career, the formative period of his professional life, by an atmosphere of exaggeration, misrepresentation and falsehood, as to other schools and teachers, neither worse nor better than his own. Without an hour's training as to the ethics of his profession, or business methods, or even a suggestion as to the duty or value of society membership, our young graduate leaves his alma mater probably conscious that he is none too well qualified for the duties of his high calling, but anxious to learn, and especially craving the practical knowledge which he believes will come with experience, and from association with his professional brethren.

(To be continued.)

Coleman County (Texas) Medical Society.

This society has been organized according to the plan of the American Medical Association. Dr. Newton Long, Santa Anna, was elected president; Dr. Samuel A. Lowrie, Silver Valley, vice-president, and Dr. James G. Pope, Coleman, secretary and treasurer.

Allamakee County (Iowa) Medical Society.

Physicians of Allamakee County met in Lansing, August 4, and formed a county medical society with the following officers: Dr. L. C. Myers, Rossville, president; Dr. E. J. Gable,

New Albin, vice-president, and Dr. John Huecker, Lansing, secretary and treasurer.

Adair-Russell County (Ky.) Medical Society.

Dr. James G. Carpenter, Stanford, Ky., councilor for the Seventh District, has organized this society in accordance with the suggestions of the American Medical Association, with 15 charter members. The following officers were elected: Dr. Uriah L. Taylor, Columbia, president; Dr. William Blair, Glen's Fork, vice-president; Dr. James R. Walford, Montpelier, treasurer; Dr. James S. Rowe, Jamestown, secretary, and Drs. R. D. Havions, Russell Springs, Joel B. Scholl, Jabez, and W. R. Grissom, Columbia, censors.

Barron-Gates-Polk County (Wis.) Medical Society.

At a meeting of the Barron County Medical Society at Barron, August 13, the organization was disbanded and an inter-county society formed embracing the counties of Barron, Gates and Polk, with the following officers: President, Dr. Olaf M. Sattre, Rice Lake; vice-presidents, Drs. Clark C. Post, Barron; W. F. O'Connor, Tony, and Herbert B. Commett, Amery; state delegate, Dr. Gentz Perry, Amery; censors, Drs. Axel Em Hedback, Barron; Charles R. Hudgel, Ladysmith, and Abraham L. Wells, Clear Lake. The new society will be auxiliary to the state and national societies.

Societies.

American Eclectic-Therapeutic Association.—The thirteenth annual meeting will be held at the Hotel Windsor, Atlantic City, N. J., September 22, 23 and 24.

Medical Society of Virginia.—The thirty-fourth annual meeting will be held in Roanoke, September 15, 16 and 17, under the presidency of Dr. John N. Upshur, Richmond.

Russell Springs (Ky.) Medical Society.—At the annual meeting recently held Dr. Joel B. Scholl, Jabez, was elected president; Dr. Lewis F. Hammonds, Dunnville, vice-president, and Dr. L. D. Hammond, Irvine's Store, secretary and treasurer. The next meeting will be held in Columbia, in August, 1904. The feature of the meeting was an address by the president on "Professional Union," as a result of which the Adair-Russell County Medical Society was organized.

American Pharmaceutical Association.—At the fifty-first annual meeting held at Mackinac Island, Mich., August 4, the following officers were elected: President, Lewis C. Hopp, Cleveland; vice-presidents, W. C. Alpers, New York; A. R. Rohring, U. S. M. and P. H. Service, and Dr. Otto F. Claus, St. Louis; treasurer, S. A. Shephard, Boston; general secretary, Charles Casperi, Jr., Baltimore; reporter on the progress of pharmacy, C. Louis Diehl, Louisville, Ky.; council, Leo Eliel, South Bend, Ind.; George F. Payne, Atlanta, Ga.; E. G. Eberle, Dallas, Tex.

BRITISH MEDICAL ASSOCIATION.

The Seventy-first Annual Meeting, held at Swansea, July 28, 1903.

(By Our Special Representative.)

(*Continued from page 512.*)

On Wednesday and Thursday, July 29 and 30, the representative meeting considered the lengthy report of the council, which, as one item, reported the continued prosperity of the association. At the close of 1902, owing to deaths and arrears of subscriptions, the actual membership showed a certain shrinkage, but signs are not lacking to prove that the new constitution will tend to make the association a more powerful factor in the influencing of legislation for the good of the community and the profession at large, so much so that it is hoped the day is not far distant when every qualified practitioner will feel it imperative to seek membership in the association.

The Imperial Vaccination League.

The council, in view of possible legislation, realizes the great importance of guiding public opinion as to the absolute necessity of vaccination and revaccination, as the only means of stamping out the terrible scourge of smallpox, and has therefore voted the sum of $500 toward the funds of the league to further its campaign in this direction.

The Journal.

The *British Medical Journal* has continued to maintain its place among the leading medical journals of the world. The rapid progress of medicine and the more widespread interest yearly taken by members in clinical and scientific questions, making increasing calls on its space, had led the council from time to time to increase the number of pages in the weekly issue, and at the beginning of 1903 some further space was economically obtained by lengthening the columns, thus allowing more matter on each page. Special arrangements have been made also for the immediate publication of preliminary reports from the scientific workers whose researchers are assisted by the association, through its scientific grants committee. Such preliminary reports, while they will not interfere with the subsequent publication of full details in the most appropriate place, present the double advantage of affording an opportunity to the workers of establishing priority of observation, and to the members of the association of becoming promptly acquainted with the results of the latest scientific investigations and of learning the manner in which the money voted for the advancement of science is utilized.

Scientific Grants Committee.

This committee has made certain amendments of the provisions under which scholarships and grants are given. It is felt that in the future scholars should devote the whole of their time to the research work they undertake, and that scholars should not hold in addition any scholarship worth more than $250. Further, it is considered that the work both of scholars and grantees should be subject to periodical inspection, and that applicants for assistance should produce recommendations as to their fitness for undertaking any proposed research.

Special Chloroform Committee.

This committee has held six meetings since its reappointment. Further work has been carried out with the view of ascertaining the best means of estimating chloroform vapor in air, and reports on this subject have been received from Dr. A. D. Waller. The methods of estimating chloroform in liquids—for example, water, blood, etc.—were also tested, and Mr. A. Vernon Harcourt, F.R.S., presented a report on this matter. At the instance of Dr. Waller, Mr. Wells has investigated this subject by means of vacuum experiments.

Various inhalers for giving chloroform have been studied with the view of ascertaining the percentage dose in air of chloroform vapor delivered under known conditions. A report dealing with the purely practical question of the clinical use of such inhalers was presented by Dr. Dudley Buxton. The committee examined the actual use of certain inhalers, and will report on them.

The special chloroform committee was originally appointed in view of the very regrettable number of cases in which chloroform administration terminated fatally. The original terms of reference were as follows: "To investigate methods of quantitatively determining the presence of chloroform in the air and in the living body"; the ultimate object laid before the council of the British Medical Association by Sir Victor Horsley being to determine, if possible, what is the minimal dose of the drug which would secure an adequate anesthesia for operations, and at the same time not endanger life.

The committee is unanimously of the opinion that the effect of chloroform varies in proportion with the amount of chloroform in the mixture of air and chloroform administered, and with the rate and depth of respiration.

As regards individual differences, there is no doubt that different subjects present varying degrees of susceptibility to chloroform, as notoriously occurs in the case of alcohol; but the committee considers that the vague expression, "idiosyncrasy," ought not to be accepted in explanation of a fatal accident if the method of administration involves considerable fluctuations of the quantity of chloroform absorbed per unit of time.

A considerable amount of time has thus been devoted to the question of dosage, and it is believed that quantities of chloroform varying between 0.5 per cent. and 2 per cent. are sufficient for the induction and the maintenance of narcosis. It will be seen from Dr. Dudley Buxton's and Mr. Tyrrell's observations that for ordinary purposes about 1 per cent. of choloroform vapor is sufficient for maintenance of narcosis.

Any apparatus for continuous administration should afford means of quickly and easily augmenting and diminishing the proportion of chloroform in the mixture of chloroform and air inspired.

The committee continued its examination of the quantitative determination of chloroform in liquids. After trying various plans Mr. Harcourt found that the best results were obtained by using a saturated solution of urea in water, and mixing this with an equal volume of the blood, according to a plan suggested by Mr. Ramsden. By employing this method in two cases the blood remained fluid during the heating and more than 90 per cent. of the chloroform was accounted for.

SUMMARY OF INVESTIGATIONS INTO METHODS.

As regards most accurate methods for determination of the amount of chloroform in air and liquids the committee now is in a position to recommend the following as trustworthy:

(*a*) In air. (1) The combustion method by incandescent wire (Vernon Harcourt's method). (2) Combustion by magnesia or lime.

The committee also further considered the employment of Dr. Waller's oil absorption method and the determination of chloroform in air by the estimation of the density of the mixture.

(*b*) In liquids. Displacement of the chloroform from the liquid by heating it for several hours while air bubbles through and subsequent estimation of the chloroform vapor thus given off.

PROPOSED FURTHER INVESTIGATIONS.

The committee has postponed the estimation of chloroform in the solid tissues and to continue its endeavor to obtain an apparatus which shall deliver a known percentage of chloroform vapor. Further, the committee hopes to determine during the coming year the physiologic effects of the lower percentages.

Finally, by the same plan of research, it may be expected that the important question of accumulation or non-accumulation of chloroform in the tissues during constant chloroform absorption which is under investigation will receive elucidation.

Report of Committee on the Vaccination Acts.

The vaccination committee recommended the following:

1. That revaccination be made compulsory by law, and that it be performed between the ages of 10 and 13 years.
2. That both primary vaccination and revaccination be subject to the same provisions for conscientious objection as in the present vaccination act, but that the procedure for exemption should be more strictly defined in any future legislation.
3. That the vaccination act should be administered directly by a department of the local government board.
4. That in future vaccination legislation no certificate of successful vaccination should be accepted unless it contains a statement as to the number and area of the vesicles produced.
5. That all lymph shall be supplied by government, or by private establishments under government supervision and guarantee.
6. That every private practitioner furnishing vaccination authority with certificates of successful and efficient vaccination, satisfying a standard fixed by the local government board, should receive a suitable fee for each such certificate.

The question of vaccination and revaccination, as well as a compulsory act relating thereto, elicited considerable vigorous discussion in the representative meeting, the matter being finally referred back to the council.

We present herewith abstracts of some of the more important papers read before the various sections of the association.

In the surgical section an interesting paper was presented by Mr. G. H. Makins, London, entitled:

Practical Experience Regarding the Most Satisfactory Methods of Performing Intra-Abdominal Anastomosis.

The following is from the author's abstract of his paper:

A.—WHICH VARIETY OF ANASTOMOSIS IS THE SAFER AND TO BE GENERALLY PREFERRED?

(*a*) Axial (or end-to-end). Gives ideal result both from physiological or cosmetic point of view—one line of suture only with corresponding limitation of area of possible leakage nutrition—cicatricial contraction—diaphragm formation.

(*b*) Lateral anastomosis. Natural method—plane peritoneal surface obtainable: size of communication at the command of surgeon: no danger of diaphragm formation; may be made remote from field of operation.

Three lines of suture needed: risk of leakage from closed ends.

(*c*) Lateral implantation. No risk of diaphragm; two lines of suture only; iso-peristalsis assured.

RESULTS OF AXIAL AND LATERAL UNION RESPECTIVELY.

Axial. St. Thomas' statistics for all causes, 53 per cent. mortality. Littlewood, eleven enterectomies for carcinoma of large bowel, 27.27 per cent. mortality. One stitch failure in eleven.

Von Eiselsberg twelve resections for intussusception followed by axial ileo-colostomy, 25 per cent. mortality.

Lateral safer than axial; more suitable for large intestine; reasons. St. Thomas' recent statistics, 30.7 per cent. mortality.

Schloffer ileo-colostomy, ten cases, mortality 30 per cent. Ileo-colostomy with resection, eighteen cases, with 44 per cent. mortality. Roskoschny, thirty-four short circuit operations, 20.5 per cent. mortality. St. Thomas' resections for carcinoma of large bowel, twenty; axial, twelve, with 50 per cent. mortality and five fecal fistulæ; eight lateral unions, with 25 per cent. mortality. Fuchsig sixteen lateral anastomoses, with 37.5 per cent. mortality; twenty-four axial unions, with 54.16 per cent. mortality.

Gastro-enterostomy general mortality from all causes does not exceed 30 to 40 per cent., and stitch failures much fewer; thus, Schloffer, seventy cases, with no stitch failure; St. Thomas', forty-two cases, with two stitch failures; Mayo Robson, one hundred and three cases, with no stitch failure.

B.—GENERAL CONSIDERATION, AFFECTING ANY METHOD OF OPERATION.

Preliminary preparation; treatment of peritoneal cavity; temporary treatment of opened bowel, with the object of preventing infection; clamps; omental grafts; drainage; after-treatment.

C.—WHAT METHOD OF UNION SHOULD BE CHOSEN?

Requirements of any method of suture. Security; even coaptation of a sufficient peritoneal surface; rapidity in application; avoidance of the production of a diaphragm; protection as far as possible of the structures of the bowel wall itself from infection; the avoidance of any complete perforation of the bowel wall.

(*a*) Suture aided by some means of mechanical support. Mayo Robson's bobbin taken as a type.

(*b*) Coaptation by mechanical devices. Murphy's button taken as a type; advantages; objections to method. Results obtained by Dr. Murphy, 863 operations, with 261 deaths, a mortality of 30.24 per cent.

The author quoted a mass of statistics on all his points.

Vaccination Acts and Smallpox Prevention.

In the section on state medicine the chairman, Dr. John McVail, Glasgow, in his address discussed this subject. He pointed out that medical men had no final responsibility for the action or inaction of the government. Physicians have much less occasion than the public to worry over parliamentary delay in the prevention of smallpox. To medical men the value of vaccination was not a matter of opinion, but of knowledge. He urged that when smallpox threatened the country the local government board should have power to issue special regulations. A matter of great importance was that of the spread of disease by tramps, and it was a question whether in the case of tramps compulsory vaccination should not be made absolute, but at any rate if any regulations were enforced they should be applicable to all tramps in the suspected area, and should not merely apply to "contact" cases. The speaker expressed the view that it was quite possible that the legislature would refuse to exclude vagrants from the operation of the exemption clause. In such a case the only suggested alternative was that tramps should be compulsorily detained. He pleaded that the amplest powers of inspection should be allowed in regard to places infected by tramps, and also of tramps themselves. This, it might be urged, would be an interference with the liberty of the subject, but it would also be most useful in the detection of smallpox. The speaker urged that in cases of outbreak local sanitary authorities should have the fullest powers; at the same time they must not forget that the object of legislation was not to punish antivaccinators, but to promote vaccination. In conclusion he urged the importance of revaccination, and stated that the opponents of vaccination had been allowed to do far too much, while the solid body of opinion in the country that favored vaccination had done far too little.

DISCUSSION.

Dr. Drysdale urged that medical men should do more to inculcate the doctrine that vaccination did prevent smallpox, and also that revaccination was undoubtedly necessary. In support of the latter the speaker pointed to Germany, where epidemics of smallpox were unknown—an immunity which

was due to the fact that children were vaccinated in infancy and again before attaining the age of twelve. The speaker expressed the view that it would be a great advantage if such a custom became habitual in Great Britain.

DR. MOLE, Gower, said he thought the medical profession were agreed that four vaccination marks were more effective than a smaller number. Some mothers considered such a number too severe, and instead of going to a public vaccinator took their children to a private practitioner, who made one mark and perhaps charged one shilling for it. The speaker expressed the opinion that every private practitioner should be supplied with lymph free in the same way as public vaccinators.

DR. T. GARRETT HORDER, Cardiff, urged that the powers now possessed by the boards of guardians should be transferred to the sanitary authorities. If this was done he felt convinced that it would tend to the juvenile population being more effectively protected against the ravages of smallpox. Everyone was aware that a large number of people escaped vaccination, and it was only in the event of an outbreak that these children were discovered. During the year 1901 5,206 births were registered in the borough of Cardiff, of which 503 children died unvaccinated, while of the remainder 3,597, or 76.1 per cent., were successfully vaccinated; 69 certificates of conscientious objections were granted, equal to 1.4 per cent. of births, and 933, or 19.7, were unaccounted for. Referring to the relation of the public vaccination officer to the private practitioner, he would like to point out that the public vaccinators had nothing to do with the framing either of the act or the local government board regulations. For his own part he had always advocated the system of making public vaccinators officials whose sole duty would be to look after the vaccination of the infants residing in the districts to which they are appointed. The speaker strongly urged that all children should be operated on before leaving school. The best and surest way of discovering unvaccinated children was to visit all schools periodically, and have the children's arms inspected. If after several visits it was found that a considerable number were not vaccinated a law should be made providing that no child should be admitted into an elementary school who had not been vaccinated. Any parent who refused to have his child vaccinated or to obtain a certificate of exemption ought to be prosecuted. In conclusion Dr. Horder hinted that private practitioners were apt sometimes to keep their lymph too long a time before making use of it.

DR. JONES MORRIS, Portmadoc, gave some interesting facts regarding his experiences as a public vaccinator in North Wales, and complained of the way in which public vaccinators were often treated by the guardians. In his view, there was no need for the general practitioner to feel envious of the public vaccinator.

DR. EBENEZER DAVIES, Swansea, referred to the recent smallpox outbreak in Swansea. There were some 200 cases, 33 of which proved fatal. They had not much difficulty in the town in regard to active opposition to revaccination, but during the outbreak they had a good deal of difficulty with regard to "contacts," concerning which they could not very well complain. The outbreak emphasized the need of revaccination of persons before they reached the wage-earning age. When they asked the "contacts" to be revaccinated they complained that they could not afford to risk being incapacitated from work by a bad arm. In conclusion the speaker stated that they had 14,000 people revaccinated in Swansea during the outbreak, and not one of these took the disease.

DR. MORRIS, Neath, said he should like to see taken up the question of prevention of smallpox in connection with tramps and common lodging-houses. He thought that the time had come when the government should take more active measures in dealing with the tramp nuisance. They ought to have tramps under a system of passports.

REVACCINATION RESOLUTION.

Ultimately two resolutions were passed. The first, proposed by the chairman, pressed on the council the importance of bringing before members of parliament throughout the country, by means of local deputations and representations, the necessity of further legislation for vaccination and revaccination. The second resolution, proposed by Dr. Drysdale, was as follows:

Considering that of late years there have occurred, in several cities of the United Kingdom, several epidemics of smallpox, while in Germany, since 1875, such epidemics have been unheard of on account of the fact that infants are vaccinated and that children are revaccinated before their twelfth year, this meeting is of opinion that all children should be vaccinated in infancy and revaccinated at the age of 10 or 12.

(*To be continued.*)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Alkalies in Atony of the Stomach.

In this department, August 5, page 387, an outline of the treatment of hyperchlorhydria is quoted from A. A. Jones. We state: "He advises against the administration of alkalies before meals unless there is co-existing atony." A correspondent asks: "Suppose there is atony, what would be the good effects obtained by giving alkalies before meals?" We think our correspondent misconstrues Dr. Jones. We infer that Dr. Jones means simply that if atony exists, alkalies will do less or no harm. We do not understand that Dr. Jones advises alkalies even in atonic cases.

Hemorrhoids.

Preissman, in *Rev. Francaise de Med. et de Chir.*, recommends the following combination containing potassium iodid, glycerin and iodin in the treatment of hemorrhoids:

℞.	Pot. iodidi	gr. xxx	2 |
	Iodi (pure)	gr. iii	|20
	Glycerini	ʒi	30 |

M. Ft. solutio. Sig.: Thoroughly cleanse the parts and apply locally on absorbent cotton. The solution in some cases is applied in greater strength as follows:

℞.	Potass. iodidi	gr. lxxv	5 |
	Iodi (pure)	gr. xv-ʒss	1.-2 |
	Glycerini	ʒi	30 |

M. Sig.: Apply locally.

Acute X-Ray Burns.

Burns produced by the *x*-ray are becoming more and more a grave subject for consideration, as the numbers increase, both on account of the severity of the burns in some cases and the stubbornness to treatment even in the mild cases. Even those who have become most familiar with the *x*-ray have sustained such severe burns as to disfigure them for life.

M. F. Engman, in *Inter-State Med Jour.*, has had occasion to treat several cases of this character, all of which were of the second degree or milder. Infection and ulceration were not present, the chief indications for treatment being the severe itching, to assist repair and to keep the surface aseptic. The following combination was used by him as a dressing, which seemed to be admirably suited to the cases:

℞.	Acidi borici	ʒiss	45 |
	Zinci oxidi		|
	Amyli		|
	Bismuthi subnit.		|
	Olei olivæ, āā	ʒi	30 |
	Aquæ calcis		|
	Lanolini, āā	ʒiii	90 |
	Aquæ rosæ	ʒiss	45 |

M. Sig.: Apply locally to the affected areas on gauze.

The powder should be rubbed up in a mortar with the lanolin. The olive oil and lime water are well mixed and slowly added to the bismuth and lanolin mixture. The rose water should be added last and a creamy paste is the result. One or 2 per cent. of carbolic acid may be added if the pruritus is excessive.

It should be applied on several thicknesses of gauze over which a sheet of gutta percha is placed to prevent evaporation. This paste is cooling to the parts on account of the amount of water present.

Round Worms (Ascarides).

The following outline of treatment is recommended by Pollard in *Med. Record* in the removal of round worms:

℞. Olei chenop. anthel. 3i 4
Ext. spigeliæ et sennæ flu. ....℥ss 15
Santonini ....gr. viii 50
Pulv. acaciæ 3i 4
Syr. rhei arom. ....℥i 30

M. Sig.: Shake and take one teaspoonful an hour before each meal. After the last dose the following should be taken:

℞. Olei terebinthinæ ....gtt. x 65
Olei ricini ....℥ss 15

M. Sig.: To be taken at one dose.

To children four or five years of age the following combinations are of service in the removal of round worms:

℞. Ext. spigeliæ flu.
Ext. sennæ flu.
Syr. simplicis, āā....℥ss 15

M. Sig.: One teaspoonful night and morning; or:

℞. Ext. spigeliæ flu. ....℥ss 15
Santonini ....gr. v 30
Ext. sennæ flu. ....℥ss 15

M. Sig.: One teaspoonful twice a day; or:

Hydrarg. chloridi mitis ....gr. iss 09
Santonini ....gr. ii 12
Sacchari lactis....gr. xv 1

M. Ft. chartula. Sig.: To be given in honey, at one dose to a child three years old or over.

The following combination is sometimes recommended in the form of an enema in the treatment of ascarides:

℞. Olei cajuputi ....m. xx 1 30
Magnesiæ levis....gr. x 65
Mucilaginis 3iv 15

M. Sig.: At one dose in the form of an enema; or:

℞. Liquoris calcis ....℥iv 120
Decoct. altheæ ....℥i 30

M. Sig.: As an enema.

Dipsomania.

The following combination is recommended by Mann in *Med. Record* in the treatment of dipsomania:

℞. Quininæ sulph.
Zinci oxidi, āā....gr. ii 12
Strych. sulph. ....gr. 1/40 0015
Acidi arsenosi ....gr. 1/100 0006
Pulv. capsici ....gr. ii 12

M. Ft. pilula No. i. Sig.: One such pill three times a day.

Copper Arsenite in Enteric Diseases.

Haslam, according to an abstract in *St. Louis Courier of Med.*, ascribes beneficial qualities to the arsenite of copper in diseases of the intestinal tract. He recommends it in typhoid fever, giving it in doses of gr. 1/100 (.0006) every hour. He believes, by the administration of this preparation, that the tongue and mouth show improvement, and that the disease is shortened a few days.

In the ordinary diarrheas he advises the following combination:

℞. Cup. arseniti ....gr. 1/100 0006
Acidi tannici ....gr. 1/20 003
Pulv. opii ....gr. 1/40 0015
Pulv. camphoræ 1/40 0015
Pulv. cretæ comp. ....gr. i 06

M. Ft. capsula No. i. Sig.: One such every three or four hours.

Painful Menstruation.

W. L. Downing, in *Med. Fortnightly*, dwells at length on the pathology and symptoms of disturbed and painful menstruation. Dysmenorrhea, according to the author, may be due either to a neuralgia of the uterus or ovaries, or may be brought about by some mechanical obstruction due to flexion or version of the uterus.

In the neuralgic variety due to uterine irritability cimicifuga is said to produce the most excellent results and to give speedy relief, given as follows:

℞. Tincturæ cimicifugæ ....℥i 30

Sig.: Ten to thirty drops in hot water every hour until relieved; then every three or four hours.

If the pain is due to ovarian irritability pulsatilla is recommended, given in five-drop doses, in hot water, every hour until relieved. These preparations may be begun one or two days previous to the usual time for menstruation.

If mechanical obstruction is the cause due to pathologic changes, preparations must be used, which are anodyne, sedative and antispasmodic in character. In these cases he recommends viburnum prunifolium given in hot water before meals, a few days previous to the attack and administered as often as every hour during the attack. This preparation should be continued three times a day for several weeks.

The bowels must be well regulated by the aid of saline laxatives or a combination of podophyllin and leptandrin, of each gr. 1/4 (.015), is recommended.

Glycerin vaginal tampons applied twice or three times a week are of value in relieving the pelvic congestion and giving comfort to the patient.

A combination containing 10 to 20 per cent. of ichthyol in glycerin is of even greater service applied locally on tampon. He also emphasizes the importance of the vaginal douche in relieving the soreness and tenderness due to cervical ulceration, endometritis, metritis, ovaritis, etc. Two or three gallons of water as hot as can be borne by the patient should be used at night and continued for a considerable length of time. Cervical dilatation must be resorted to, previous to menstruation if narrowing of the internal os be present, and flexions corrected, if possible, when present as a causative factor, by proper supports. If polypi block up the outlet from the uterus, dilatation must be carried out and the polypus snared off.

Furuncle.

The employment of a solution of iodin in acetone is recommended by Gallois and Courcon in *Bul. Gen. de Ther.*, in the abortive treatment of furuncles. Acetone, it is said, will hold three or four times as much iodin in solution as will alcohol, and consequently is more effective. The following combination is used:

℞. Iodi (metallic) 3i 4
Acetone 3iiss 10

M. Ft. solutio. Sig.: Paint the affected area once or twice daily.

In many cases, it is asserted, boils may be aborted by applying the solution early.

Empyroform in Diseases of the Skin.

This preparation, which is a combination of tar and formaldehyd has been used successfully by Neisser, according to the *Ther. de Gegenwart*, in the treatment of the different forms of eczema. It may be used in the form of a paste in five, ten, twenty or fifty per cent. strength combined with zinc or lanolin. The following formula has also been recommended:

℞. Empyroform ....℥ss 15
Talci venet.
Glycerini
Aqua destil.
Spts. vini, āā....3iiss 10

M. Sig.: Shake well and apply locally to the affected parts.

In the form of a tincture, it may be used as follows:

℞. Empyroform 3i-iiss 4.-10
Spts. chloroformi
Tinct. benzoini, āā....℥iss 45

M. Sig.: To be painted over the affected areas.

This preparation is said to possess advantages over the ordinary tar preparations in that it is very grateful to the patient, no irritative symptoms arise, no systemic symptoms of intoxication are present. It is a powerful antipruritic and is odorless. The advantages of this new combination over the ordinary tar preparations are supposed to be due in a great measure to the formaldehyd present.

Medicolegal.

Care Required in Removal of Pauper in Distress.—The Supreme Judicial Court of Maine holds, in the case of Merrill vs. Bassett, that the care to be used in removing a person in distress from one town to another under the pauper law is that care and prudence which a reasonably careful and prudent man would exercise under the circumstances of a like situation. The test by which to determine whether due care and prudence have been exercised by one charged with the duty of removal of a person in distress from one town to another, in ascertaining the ability of the pauper to bear the strain of the journey, is the means employed and effort made to find out, rather than the actual physical condition itself. A day affording proper weather conditions should be selected; the pauper should be furnished with suitable garments to protect her, considering as well her physical condition as also the state of the weather; and suitable conveyance, in a careful and prudent manner, should be provided.

Liability of Railroad in Association for Services.—The Supreme Court of Florida, Division B, holds, in Florida Southern Railroad Company vs. Steen, that, where railroad companies owning and operating their several roads enter into a voluntary association, and a hospital and relief department is formed by the association for the several companies, and such department is operated in connection with the business of each company—employes of each company being required to be members of such department, and to contribute regularly to such department sums deducted from their wages by the company for the privilege of such membership—one of such companies is responsible for the compensation of a physician employed by its employes, in pursuance of the regulations of the department, to treat another employe injured by an explosion in the shops of such company. But a physician employed, in pursuance of the authority conferred by the regulations of the relief and hospital department of a railroad company, to treat an injured employe in an emergency, where the company's surgeon could not be reached, who was employed for no definite period of time, can not recover for services rendered after being notified that his services were no longer needed, as the hospital surgeons were then ready to take charge of the case and properly treat the patient in the company's hospital.

Admissibility of Non-Expert Opinions On Sanity.—In Queenan vs. Territory of Oklahoma, where a non-expert witness, a lawyer who knew the prisoner, charged with murder, quite well, it was ruled, could not state an opinion formed after the killing as to his mental condition at that time, but might state any condition that existed when he saw the prisoner on the day before the killing or any impression that it made on his mind as to the prisoner's condition, the Supreme Court of the United States says that some states exclude such opinions, even when formed at the time. But it is impossible for a witness to reproduce all the minute details which he saw and heard, and most witnesses make but a meager and halting effort. Therefore, in this, as in many other instances, after stating such particulars as he can remember—generally only the more striking facts—an ordinary witness is permitted to sum up the total remembered and unremembered impressions of the senses by stating the opinion which they produced. To allow less may deprive a party of important and valuable evidence that can be got at in no other way. But, on the other hand, to allow more, to let a witness who is not an expert state an opinion on sanity which he has formed after the event, when a case has arisen and become a matter of public discussion, must be justified, if at all, on other grounds. It is unnecessary to lay down the rule that it never can be done, for instance, when the opinion clearly appears to sum up a series of impressions received at different times. It is enough to say that, at least, it should be done with caution and not without special reasons.

Employment by County Physician of Other Physician.—Article 4339 of the Revised Statutes of Texas of 1895 makes it the duty of a county physician to establish, maintain and enforce local quarantine for his county whenever declared by proclamation of the commissioners' court; to furnish supplies, select medical assistants, guards and perform all other duties coincident to a reasonable, economic and consistent quarantine. Article 4340 provides that whenever the commissioners' court of any county has reason to believe that they are threatened with the introduction or dissemination of a dangerous, contagious or infectious disease that can and shall be guarded against by quarantine, they may direct their county physician to declare and maintain said quarantine; to establish, maintain and supply stations or camps for those held in quarantine; to provide hospitals, tents or pest-houses for those sick of contagious and infectious disease; to furnish provisions, medicine and all other things absolutely essential for the comfort of the well and the convalescence of the sick. The county physician shall keep an itemized account of all lawful expenses incurred by local quarantine and his county shall assume and pay them as other claims against the county are paid. But, in the case of Barrett vs. Hill County, an action brought by a physician to recover for services rendered to certain smallpox patients under an alleged employment for the purpose by the county physician, the Court of Civil Appeals of Texas holds that the county physician had no authority to make a contract binding on the county, unless the commissioners' court had declared quarantine. It says that the articles mentioned clearly indicate the purpose not to authorize the county physician to incur liability on behalf of the county in such cases except when quarantine has been declared by the commissioners' court. This limitation on his authority was doubtless prompted by a desire to guard the county against extravagance in these epidemics, which, at best, are expensive enough; and to place all expenditures under the supervision of the commissioners' court.

Classification of Physicians—Right to Practice.—District Judge Bryant, delivering the opinion of the United States Circuit Court in the case of August Busch & Co. vs. Webb and others, says that the question to be determined was, can a state take away from a physician his right to practice his profession because he has some other business than that of medicine? He says that he recognizes the right of the legislature to classify physicians, provided the classification is based on sound public policy, and is a reasonable classification. To illustrate: It would be competent for the legislature to say that no physician who has been convicted of a crime should be allowed to practice his profession, or to pass any other reasonable regulation, although, apparently, it might discriminate against persons in the same class or profession. But the judge says that he apprehends that, wherever such classification is made it must be made on the ground of public policy, and for a reason that would attach to the party thus excluded either moral turpitude or incompetency. Where such classification is attempted, and for such reasons, the court will uphold it. But is it true that the legislature can arbitrarily deprive any citizen of his right to pursue his chosen profession, and to its fullest extent, where the discrimination is made solely because he is engaged in some other lawful business which in no wise attaches to him unfitness to practice his profession or moral turpitude? The physician's calling is one that requires long preparation and scientific information not possessed by people generally, entailing on him much expense and years of close study to qualify himself to properly perform his duties as a physician. His calling is of that nature, being one of confidence. He obtains the secrets of his patients as to physical ailments, of whatever character they may be, and therefore the legislature has the power, on grounds of public policy, to guard strenuously the individuals that are allowed to practice medicine, and they have the right to classify and discriminate for good cause, but that does not carry with it the power of arbitrarily discriminating against any member of the medical profession, unless, as so often stated, it is for incompetency or moral turpitude, which public policy requires should be enforced. Here, there was a graduate of a medical school, whose

main business was that of postmaster, though he still practiced his profession as a physician, who averred that in such practice, in some cases, it was necessary that his patients should be supplied with alcoholic stimulants. And as applied to these facts, the court holds unconstitutional and void that portion of the local option law, Article 3385 of the Revised Statutes of Texas of 1895, which reads: "Provided, that a physician who does not follow the profession of medicine as his principal and usual calling shall not be authorized to give the prescription provided for in this article."

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal.

August 13.

1 *The Present Status of the Surgery of the Prostate Gland. Paul Thorndike.
2 *Preliminary Report of Five Cases of Renal Decapsulation. J. Bapst Blake.
3 *Rupture of the Quadriceps Extensor Femoris Muscle. Halbert G. Stetson.
4 Report of a Case of Aphasia as a Complication of Measles. Warren R. Gilman.

1. **Surgery of the Prostate.**—Thorndike reviews the operations and concludes that no patient should be allowed to suffer for lack of proper treatment. If there is still a place for the catheter many patients can be made comfortable and kept so by its systematic proper use. But all who can not be thus relieved are fit subjects for operation. The time for operation is as soon as the inadequacy of palliative treatment is shown. The operation of choice is always prostatectomy, but only in persons whose general condition make them fit surgical risks. That is rare after 65 years of age. For all others the Bottini operation can be offered as one attended with little risk to life, short convalescence and a good prospect of such a degree of improvement as will obviate the further use of the catheter.

2. **Renal Decapsulation.**—Five cases operated on by Edebohls' method are reported by Blake, who describes his technic and the method of operating. Two of the cases are practically well, though only some months have elapsed since the operation. Two died respectively in six days and six months after the operation, the latter from tuberculosis of the kidney and general tuberculosis, the former from shock and failure to recover from the operation, for which he was in bad shape. One patient has apparently not improved. In the two cases that are apparently cured, traces of albumin and casts are still found. He thinks if the patients would abstain from alcohol entirely it might be followed by the disappearance of albumin and casts in the urine. In other respects they feel as well as ever, and are following their usual occupations.

3. **Rupture of the Quadriceps Extensor Femoris Muscle.**—This accident is considered rare by Stetson, but still it is likely to occur. He thinks the diagnosis should not be difficult if seen early. If rupture is only partial the tendency is toward recovery under mechanical treatment. If complete the operative method would seem to be preferable, other things being equal. The operation consists in cutting down on the separated ends and uniting them either with silkworm gut, kangaroo tendon or silver wire. If the rupture is too close to the patella for suturing the tendon, the upper portion of the tendon should be sutured to the bone itself. He quotes Walker's conclusions that where the joint is apparently not opened and there is not much effusion and the separated ends can be brought together, mechanical means may be favorably considered and ought to bring about a recovery in most cases in from nine to twelve months. Aseptic surgery in suitable cases, however, considering the age and vitality of the patient, may produce better results. Where the separation is greater than one and one-half inches or mechanical treatment has failed, operation is indicated. The element of time in the operative method is an important consideration. A case is reported.

8 *What is Epilepsy? J. W. Wherry.
9 *Treatment of Tetanus by Means of Subcutaneous Injections of Carbolic Acid—Baccelli's Method—with a Review of Seventy-five Cases from the Literature. Douglas Symmers.
10 Congenital Cystic Kidney. Walter E. Toble.

5. **Rubella.**—Dillingham's paper is largely a discussion of the diagnosis of rubella, which he says is sometimes very difficult as regards measles, though not so much so with other diseases.

6. **Enteroptosis.**—Brown gives the history of the subject, the anatomic conditions and the literature as regards theories. He specially notices Keith's contribution in the *Lancet* of March 7 and 14, 1903, and his idea of the relation of enteroptosis to the respiratory function. He roughly classes the theories into three groups, as follows:

1. The condition is congenital and is due to an inherent weakness of the tissues which support the abdominal viscera; such factors as clothing, trauma, disease, etc., are not the primary causes of the condition, but simply contributory causes, which bring out and accentuate the inherited tendency; 2, the condition is due to the pressure of clothing, trauma, weakness of abdominal walls, various diseases associated with marked loss of strength or weight, various spinal and thoracic diseases, pregnancy, and parturition, abdominal tumors of various kinds; in other words, a number of conditions, each of which, however, has as its results the weakening of the various visceral supports, due in some cases to pressure, in other cases to adhesions, in other cases to trauma, and in still other cases to a marked diminution in the supporting power of the abdominal walls; 3, that each of the foregoing may be the primary causes of the condition; in other words, that there is both an acquired and a congenital form of enteroptosis. A careful consideration of the various theories evolved and of the cases of enteroptosis described in the literature and met in our own experience should, I think, make us take this third view. As to the exact way in which the ptosis is produced there are a number of possibilities, but the suggestions of Keith in this connection—that is, that the diaphragm is the most important factor in the production of this condition—should receive most careful consideration.

8. **Epilepsy.**—Wherry remarks that epilepsy is a condition of autointoxication spasm resulting in autoasphyxia. It is the result of a vasomotor spasm causing asphyxia of the brain, and so far as the symptom of epilepsy is concerned, is the same as convulsions occurring in asphyxia from other causes, as in hanging. He says epilepsy is a state of autoasphyxiation from a condition of physiologic strangulation or suffocation, except that the cause manifests itself through obstruction to circulation rather than to respiration. The ultimate effect in both cases is depriving the brain of oxygen. He calls this the explanation of epilepsy shorn of all mystery.

9. **Tetanus.**—Baccelli's method of the treatment of tetanus by subcutaneous injections of carbolic acid is taken up by Symmers, who gives to a large extent the history of the treatment of this disorder by this method, reviewing 75 cases. He says that in all suspicious cases and wherever the bacillus of tetanus is known to exist, the areas should be excised or the extremity amputated; if this is impracticable the wound should be cleansed of all foreign substances and saturated with oxygen by means of hydrogen dioxid or the injection of pure oxygen gas; following which it should be flushed with boric acid or saline solution, followed in turn by potassium permanganate or a 5 per cent. solution of iodin trichlorid. No matter what local treatment is employed, if the wound affects an extremity, care should be used in applying permanent carbolic dressings lest gangrene develop. In establishing drainage moist iodin gauze should be employed whenever expedient. Impermeable dressings, dusting powders and caustics should never be used and such wounds should never be incised. A subcutaneous injection of antitetanus serum should be given in every case where development of tetanus is more than a remote possibility. The use of blank cartridges, firecrackers and similar creations should be more stringently regulated. In addition to the general management of the case, the patient should receive subcutaneous injections of carbolic acid along the tracks of the great nerve trunks, the injections being commenced as soon as the diagnosis is made. The body should be further fortified by the administration of the acid by the

mouth or rectum, or both, and it should be pushed to the utmost physiologic limit. Antitetanic serum should be combined with carbolic acid, and if possible given according to the method of Jacob: 5 or 10 c.c. of cerebrospinal fluid is withdrawn by a hollow needle cautiously inserted into the subarachnoid space between the second and third lumbar vertebræ, following which 5 c.c. of antitetanic serum is allowed to flow slowly in under very gentle pressure. The foot of the bed is then elevated and allowed to remain so for at least half an hour. If this can not be done the serum should be administered subcutaneously frequently and in full dose, choosing the track of the great nerve trunks after inserting the needle near or even into the sheath of one or both of the sciatic nerves, keeping the patient under chloroform so that pressure or stretching of the sheath may not increase the number of convulsions or the degree of pain. Intracerebral and subdural paths are valuable only in certain cases and no more certain than the methods described. Intravenous injection is the least rational of all because the antitoxin going directly into the right heart becomes aërated as it passes through the lesser circulation and is deprived of some of its potency. This objection has been applied to subcutaneous injections, but is still more decided as regards the intravenous method. Lastly, that absolute quiet be maintained and the use of carbolic acid, antitetanic serum and the nervous sedatives be continued for several days after the complete subsidence of spasm.

16 *Chronic Leg Ulcers. F. Ward Langstroth.
17 *Some Phases of Cranial Surgery. Gilbert G. Cottam.

11, 12, 13 and 14. **Hydrophobia.**—Taylor gives the general facts as to the etiology, pathology and prophylaxis of this disorder. He notices the pathologic lesions described by Van Gehuchten and Nélis and the advantages of the test. The importance of muzzling dogs and the use of early cauterization are insisted on, and prophylactic inoculations by the Pasteur method and their good results described. He thinks that the Tizzoni and Centanni or the Italian method of serumtherapy promises much.

Pritchard dwells particularly on the hysterical form of hydrophobia and its diagnosis from the genuine type of rabies, and points out the conditions which are more or less constant. The pseudorabies inoculation period is apt to be much shorter or longer than the true disease. Symptoms developing within a day or two after a bite are almost certainly hysterical. The order of sequence is sometimes different. There is no first or second stage, and the patients develop at once the convulsive symptoms and are apt to bark and snap, which is not the case with the genuine form. If the symptoms in any case last over seven or ten days it is almost conclusive of the non-existence of the genuine disease. It should be remembered that the pseudo-form has been fatal. Other conditions that may simulate the disorder are tetanus, though the diagnosis is generally easy, and certain cases of insanity.

Gill describes the symptoms of the furious and dumb forms. He thinks the present regulations are inefficient as regards the prevention of this disease, and criticises the Society for the Prevention of Cruelty to Animals for its practices, especially the gathering of dogs in a covered wagon to fight and bite each other, which may tend to directly spread the disease. He advocates the destruction of worthless, ownerless and vagrant dogs, and the efficient muzzling of all dogs that run in the streets and public places. The results which have been obtained by muzzling justify its enforcement. He gives the examples of England and Prussia as regards this point, and concludes with the following:

For absolute public safety the following measures are suggested: 1. To place the city dog handling under proper medical or veterinary jurisdiction; 2, to prohibit all dogs from running at large unless muzzled or, at least, muzzle all dogs in infected areas; 3, to provide separate compartments in the wagon and at the pound for each dog; 4, to provide safe and proper places for the keeping of dogs suspected of having rabies, especially if they have bitten other dogs or a person; 5, every dog bitten by a rabid animal should be destroyed, or quarantined for at least one year.

Cabot thinks that strict regulations are necessary, and it is an error to suppose that the furious type is the common one. The usual one is the dumb type, the bite of which is equally dangerous. The micro-organisms of rabies, he thinks, are fermentative in character, lying localized for at least twenty-four hours, and then infecting the system by way of the nerves and not directly by the blood. The extent of the wound is of much less importance than its position and after-treatment; a scratch may convey the infection. In the case of wounds about the face and exposed parts an anesthetic should be used if necessary and the wound scrubbed out with a brush and green soap, followed by bichlorid of mercury, 1 in 1,000, as if for an operation. Then fuming nitric acid should be carefully applied by means of a pointed glass rod and the wound dressed surgically. If no general anesthetic has been given he usually uses cocain first after scrubbing, then pure carbolic acid followed by fuming nitric acid. This should be done as early as possible, but he has found by careful experiments on guinea-pigs that it is of value even after twenty-four hours. If we can not obtain nitric acid, the actual cautery is the next best. Nitrate of silver is a very poor caustic, and should not be used. Simple scrubbing and cleansing out the wound with soap and water had some effect, saving 31 per cent. of his infected guinea-pigs. Treatment begun even after forty-eight hours is of some value, and when done within twenty-four hours, and properly, he believes it to be of more value than the Pasteur method. The dog in all cases should be kept alive and watched for a week, and if it remains well then there is no danger. If it dies, the brain should be preserved for examination and inoculation tests made. He does not describe the Pasteur method, but shows that the preliminary treatment of the wound also is to be taken into consideration when deciding on the number of Pasteur injections. He says, in conclusion, that if the disease develops do not give up hope, as one case has been known to recover. This was reported by Gowers, and Cabot considers it possible.

16. **Leg Ulcers.**—The treatment of these ulcers, most frequently due to varicose veins, are described by Langstroth. He gives a few simple rules to follow: 1. Insist on the importance of proper differential diagnosis, which is too often neglected. 2. Avoid all ointments and pastes, relying on aseptics or often, in this condition, antiseptics. 3. Always consider the local and general constitutional treatment. 4. Do not give up the case. The ulcer that will not heal is rare. In varicose ulcer we should remove the cause as far as possible. The radical and palliative treatment may be gained from any work on surgery. Therefore, only two measures are mentioned here: radical treatment, which should be considered only when the operation has entirely healed, and bandaging. He would not use a spiral reverse on the leg because it gets out of place. A properly-applied figure eight of the foot and leg, making all pressure on the up-turns, gives the best results. In very sluggish ulcers, curette the surface and incise the edges. In varicose ulcer of the chronic sluggish type, elliptical incisions around the parts will release the tension. They should be done under aseptic or antiseptic precautions. They cut the fibrous tissue and allow the formation of new capillaries and also allow the ulcer to contract toward its center. Solutions applied to ulcers, on sterile gauze, are the best applications, and he gives several formulæ for these. The saturated boric acid solution is useful where the ulcers readily become inflamed, but it is rather mild for most cases. Alum acetate in saturated solution is useful in chronic cases that have become suddenly inflamed. A 5 to 10 per cent. ichthyol solution in water is also useful. Chronic ulcers must be stimulated in order to heal and more blood must be brought to them. Some of the milder caustics may be em-

ployed at the time of dressing. Silver nitrate, brushing over the wound surface with 40 grains in solution in an ounce of water, or touching the granulated surface with the stick, is sometimes valuable. Rest in bed with elevation of the part is often useful, but should be employed as a last resort for people that have to get around about their daily work. Massage and douches of alternate hot and cold water are useful in all cases. When the ulcer has become healthy and the granulations reach close to the surface, the parts may be strapped with strips of zinc oxid plaster, ¾ in. wide, applied alternately from opposite sides, beginning below and extending well above the ulcer and not allowing the ends to meet within an inch or more. They may be left in place for a week or ten days. Skin grafting is sometimes useful, but not so much so as in cases of burns or acute conditions. If the ulcer has healed a Randolph elastic bandage should be worn indefinitely and the leg doused with cold water and rubbed with alcohol every night and morning. The constitutional treatment consists in hygienic measures, such as regulation of the diet and bowels, tonics, sometimes arsenic, etc. Syphilitic ulcers readily respond to local specific treatment. Creolin solution (half an ounce to a pint of water) is useful in overcoming the odor and removing the slough. Instead of solutions in some cases it may be well to try dusting powders, etc. The formulæ given are those for red wash, Lassar's paste, and balsam of Peru gauze.

17. **Cranial Surgery.**—Cottam remarks on the difficulties of localizing diagnosis and the value of exploratory operation in some of these cases, the avoidance of chemical antisepsis and the necessity for the most careful asepsis. The objects to be accomplished are limitation of the infection, hemostasis and relief of pressure. If this can be done through the ordinary opening, what is the use of making it larger, as is often advised? In no case should the scalp be stitched in an open fracture if the stitching interferes with the drainage in the slightest degree. Simplicity in technic is insisted on. The trephine, he urges, is an obsolete instrument, and in its place are the chisel, the ronguer and the DeVilbiss device. With these in practical hands anything can be done. They do not get out of order or break. He also puts in a word for the osteotegumentary flap as the simplest method of entering the skull for the relief of middle meningeal hemorrhage, growth or abscess or for purely exploratory purposes.

21 *Chronic Gastritis. A Clinical Study of 600 Cases. G. W. McCaskey.
22 Double Extra-uterine Pregnancy. Swithin Chandler.

18. **Jaundice.**—The points particularly emphasized by Deaver are: 1. Jaundice is absent in the majority of cases of gallstone disease. 2. Jaundice following acute gastrointestinal symptoms means a catarrhal condition of the ducts, and may be followed by suppurative cholangeitis, with marked jaundice and other symptoms. 3. Jaundice following chronic gastrointestinal symptoms is usually due to chronic pancreatitis with induration and enlargement of the head of the pancreas with or without gallstones after excluding malaria. 4. Acute obstruction of the common duct by stone furnishes the common symptoms usually diagnosed. Chronic impaction is followed by the intermittent type of jaundice without gallbladder enlargement or by no jaundice whatever. If the icterus becomes intense, fever, sweating and chills of suppurative cholangeitis will denote infection. When a patient dies in a condition of intense jaundice we speak as if a cholemia was present. Deaver thinks most of these cases die of infection and not from retention of the bile *per se*. Cholemia he defines as a train of symptoms usually beginning suddenly and ending fatally in a few days, of which the most prominent are jaundice, acute prostration and delirium or coma. The dammed-up secretions compress the liver cells and the retained bile has a deleterious effect. Fatty degeneration or necrosis follows, and with the overgrowth of connective tissue, interstitial hepatitis is produced. The bile itself, the products of the diseased liver cells and the infection of micro-organisms make altogether an autointoxication of which the exact effect is not easily comprehended. We have also various gastrointestinal disturbances such as anorexia, constipation, symptoms of nervous influences, such as disturbances of sight, like the phenomenon of yellow vision, pleuritis, slow and small pulse ascribed to involvement of the nervous apparatus, etc. The excretion of bile pigment by the kidneys must cause disease of their epithelium, and if persistent produce necrotic changes. In the early stages with a slightly yellow tinge; the urine may give no reaction to bilirubin. In the more advanced stages with marked jaundice, the absence of this reaction would indicate the relief of the obstruction. Lastly, there is a certain predisposition towards hemorrhage; epistaxis, hematemesis or intestinal hemorrhage may occur. The system may in time become accustomed to the bile, and any organic symptoms be lacking. There is no direct treatment of icterus. In inoperable cases we can relieve the itching and promote diuresis and diaphoresis in the acute form. In operative conditions, calcium chlorid in 20 or 30 gr. dose three times a day seems to have some effect in preventing hemorrhage. This post-operative bleeding is most frequently met with in jaundice due to chronic pancreatitis and malignant disease of the pancreas. After operation calcium chlorid may be administered per rectum, 30 or 40 gr. every four hours with a full dose of opium. Deaver pleads for a careful study of the icterus cases so as to be able to form a diagnosis as rapidly as possible and call for surgical consultation before the damage has become too great.

19. **Regicides.**—Spitzka's article is to be continued. In this installment he seems to think that the ordinary type of political assassin is decreasing with higher culture, and that there will be comparatively few sane regicides among the Anglo-Saxon, Germanic or French population in the future. We will have to look to the Italian, Balkan and Iberian peninsulas for the sane assassins of the future. His views as to the proportion of sane regicides are well known from his former publication, and he seems to believe that at the present peril is in the organized anarchists in civilized countries. The economic conditions met with have little to do with it. The promotors and actors in the assassination of prominent people are not suffering from economic conditions themselves. They are more often anarchist enthusiasts with the common misguided ideas about tyranny and freedom, and are not insane.

20. **Phlegmasia Alba Dolens.**—The mechanism of this trouble which is generally held to be due to thrombophlebitis is studied by Stowe. He thinks there is some probability in the hypothesis of Tilbury Fox that obstructive lymphangeitis is the hitherto unknown factor which enables thrombophlebitis in this case to produce the well-known symptoms. He thinks a reasonable position is to take the middle ground and say that thrombophlebitis is the primary cause. Increased activity of the lymph following occlusion occurs in weakened vessels producing thrombosis in a manner similar to its production in the veins. This, of course, applies only to the main vessels. The condition of the blood is to be taken into account. The treatment is mainly summed up in prophylaxis; proper care during pregnancy, putting the patient on small doses of calcium chlorid for three or four weeks prior to the expected labor and carefully inspecting the conditions immediately following placental delivery and carefully guarding against lacerations. He has found the best results for perineal protection in delivery on the side, keeping the head pressed against the sphincter, gradual dilatation of the pelvic outlet and delivering the head between pains. Asepsis is the ideal condition; when that fails we may have to fall back on thorough antisepsis. When phlegmasia dolens has occurred in spite of care, the patient should be put to bed and kept quiet and the limb raised on an inclined plane six or seven inches and enveloped in a compress of gauze retained by a roller bandage. During the acute stage much relief can be obtained by keeping the

compress as hot as can be borne. No massage should be allowed early in the disease. For the pain morphin in some form is at times indispensable; when not so severe, other drugs may be substituted. The bowels should be kept open by salines. Cardiac tonics are often indicated. When the subjective symptoms have ameliorated measures should be taken to remove the semi-solid matter from the tissues. Gentle massage and the use of dry hot-air as early as possible, which is, he thinks, one of the best measures of all. Potassium iodid or protoiodid of mercury is to be given for weeks and months. Calomel in small doses is also of advantage.

21. **Chronic Gastritis.**—McCaskey has studied the conditions as to the acidity in this disorder, and thinks that it is possible that primary hyperchlorhydria may play an etiologic rôle in its production. He does not think the condition can be excluded in the diagnosis on the ground of increased HCl. He finds that a slight majority of his patients are males and between 20 and 40 years of age. Nearly one-half the cases are farmers and housewives, about 72 per cent. follow indoor occupations, but the majority of them active ones. He calls attention to the frequent latency of the disease and to the defective motor power of the stomach, which he thinks plays an important part in the disorder. The treatment consists in careful attention to nutrition, which is generally below par, elimination, moderate gymnastics, deep breathing, hydrotherapy, general faradism, etc. Of local treatments, lavage is the simplest and most abused of all the methods. It is only advisable when there is a considerable amount of mucus or other debris. Electricity is of great help, and he would use faradism with intragastric electrodes. Another method of great value is the use of finely divided medicaments, using the Einhorn apparatus for concentrated drugs and Turck's nebulizer for the milder applications. He has also found Turck's gyromele, as lately modified by the inventor, of much value. Electric vibratory massage applied over the stomach, which may be distended with air, is also of advantage. Care should be taken against over-treatment and careful individual treatment applied in every case.

26 *Pathology and Treatment of Pneumonia. John North.
27 The Principle of Life and Cognate Things. Joseph Clements.
28 An Unusual Case of Empyema of the Antrum of Highmore. Sidney Yankauer.

23. **Mammary Cysts.**—Abbe holds that mammary cysts are much more common than is generally thought. They are frequently diagnosed as malignant, and treatment by extirpation recommended, when it is unnecessary, on the ground that if not malignant the gland is likely to become so. Formerly he himself considered them as degenerative, but of late years it has been his custom to test the nature of the tumor by aspiration before making an absolute diagnosis. Reviewing his private practice in eight years he has seen 41 cases of mammary cyst and 56 of scirrhous tumors, besides a number of innocent inflammatory adenomas, and he thinks this is not far from the average surgical experience. Two points have impressed him in this series of cases: 1. The differential diagnosis, which can be said to be easy and absolute, and 2, the cure, which can also be said to be easy and absolute. He calls attention to the deceptive hardness, which renders it impossible sometimes to determine the cystic character of the tumor without exploratory aspiration. When the tumor is found to be cystic, the withdrawal of fluid in the great majority of cases seems to be sufficient for a cure. In only 2 of his 41 cases was the cyst refilled and secondary aspiration required. He thinks it is the duty of every surgeon to test the nature of each doubtful hard tumor with an aspirating needle thrust quickly into its very center, sterilizing the skin by a moment's friction with alcohol. The results in satisfaction to the patient and practitioner, he thinks, will be all that can be desired.

24. **Prostatic Hypertrophy.**—The various methods of operating on an enlarged prostate are reviewed by Herrick, who describes the methods and discusses their merits. In conclusion he says:

1. These cases must be judged more or less individually.
2. When chronic posterior urethritis and prostatitis exist, these should receive appropriate treatment, the catheter used to withdraw residual urine, and the result carefully watched.
3. In patients in whom operation has become too hazardous, we must endeavor to improve their general condition, and, if necessary, do aspiration or perineal cystotomy under cocain, endeavoring to prepare them for radical operation or alleviate their symptoms. Advanced arteriosclerosis should also be carefully considered.
4. Our responsibility is in recognizing and properly urging operation when indicated; if it is refused we have done our duty, and the patient must abide the issue with such means as remain.
5. Palliative operations should rarely or never be done from their hazardousness and inefficiency.
6. Prostatic hypertrophy is now curable by means of an operation which, though serious, is not hazardous when undertaken in proper time and manner. Failure of palliative treatment, of course, gives hope alone through operation, but should be anticipated rather than persisted in. In general infection, especially if repeated, as in irritable cases, obstructive cases unless promptly relieved by its sound and under observation, if residual urine is increasing despite catheterization, or the patient's general health is being impaired, all indicate the time for operation.
7. Anatomically, and now surgically, the simple perineal is the direct and preferable route. Rarely suprapubic exploration or lithotomy may be advantageously added to it.
8. As statistics accumulate, we believe that radical cure may further anticipate the course of the disease.

25. **Cancer.**—Bell holds that cancer, or the elements of cancer, are present in every normal individual. The cancer entity is in its original state a normal cell, which from circumstances is altered in character and assumes a new rôle of existence, losing its benign attributes, becoming aggressive and cannibalistic, preying on its neighbors. He draws attention to the fact that epithelioma invariably retains its epithelial character, and, under conditions of enfeebled general health, may take on a malignant form, though often innocent in its first beginnings. The importance of the thyroid body to the epithelial elements is mentioned. His theory of cancer is that intestinal toxins affect this organ, disturb the balance of nutrition and set up a morbid process. He sums up the treatment in the administration of thyroid gland, supplemented by measures to destroy the saccharomycetes in the intestinal tract, which are almost invariably present in cancerous subjects, and to prevent the perpetuation of their effects on the enterotoxins. In conjunction with thyroid extract it is, therefore, advisable to administer the salicylates in one form or another, and also to relieve constipation. The diet should be modified so as to be composed largely of milk food, thyroid extract administered in 5-grain doses three times a day, and along with this, 10 to 15 grains of salicylate of sodium, and local applications used to remove all sources of irritation. If the disease has not advanced too far he thinks the condition will yield to this treatment. In conclusion he sums up the predisposing causes of cancer in the following:

1. Persistent and prolonged retention of feces containing an undue proportion of decomposing albuminous material, from which enterotoxins are derived, and by absorption conveyed to the blood.
2. The blood thus contaminated produces a depraved condition of the nervous apparatus, thereby handicapping the functional activity of the various organs, interfering with cell metabolism, and eventually culminating in anemia in young persons, or cachexia in the elder.
3. If the functions of the thyroid gland are at fault, these toxins, which otherwise would be neutralized, remain in a position capable of producing serious mischief.
4. If saccharomycetes are present in the blood, this toxic material is liable to undergo chemical changes, resulting in the formation of uric acid, when uricacidemia will result.
5. The presence of these toxins in the blood, alone or combined with uric acid, exerts a pernicious influence on cellular structures, and confers on them a predisposition to take on a malignant metamorphosis.
6. Prolonged or repeated irritation of a part is liable to rouse into malignant activity cells which otherwise would have remained dormant.
7. The vitiated condition of the blood by prostrating the physiological vitality of the various organs and cellular structures and paralyzing the *vis medicatrix naturæ* affords every facility for the new growth to establish its identity and increase its area at the expense of its environment.

26. **Pneumonia.**—North holds that our great death rate in pneumonia is due to the antiphlogistic treatment of the disease. Pneumonia is not properly an inflammation, and should not be treated as such. A light nutritious diet, and the use of quinin in 2-grain doses every two hours in the beginning to diminish leucocytosis may abort the disease if begun

promptly in full dose at the beginning. He would also use ammonium chlorid and aconite in minute doses, which is of great value. Opium or its derivatives is also used throughout the disease. He prefers svapnia to other forms, given in 1/10-grain doses every two hours, stimulating the respiratory center and acting as an expectorant. Large doses should never be given. Heroin in 1/12 grain doses is sometimes very valuable. Alcohol, strychnin, nitroglycerin, digitalis, veratrum, salicylates, creosote, derivatives, saline injections, etc., are all useful in pneumonia if used in the proper stage or to combat complications as they arise. Warm applications, cold packs and cold sponging are called for in almost every case, depending on conditions and circumstances.

31 *Mercurial Injections in Syphilis. William F. Bernart.
32 Surgery of Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

29.—See abstract in The Journal, xl, p. 1529.

31. **Syphilis.**—Bernart advocates the method of mercurial hypodermic injection in syphilis on account of its accuracy, the conciseness with which the therapeutic and physiologic lines can be drawn, the absence of gastric and kidney troubles, the rapidity of its action and its practical painlessness. The objections to it have been the alleged occasional fatality, the production of irritation and the necessity of its being carried out under the direction of a physician. The first two of these he considers of small importance and as likely to be raised against any method of treatment whatever. The fact that it requires the close personal attention of a physician is, in his opinion, one of its strongest recommendations. The alleged painfulness is, he thinks, under proper use absent. The preparation which he recommends and which he finds most useful is the following:

Mercuric chlorid	.50	(7 7/10 grs.)
Sodium chlorid	.25	(3 4/5 grs.)
Boiling distilled water	25.00	(6 1/4 drs.)
When cool add:		
Carbolic acid	.15	(2 1/10 grs.)

Of this 1 min. equals 1/50 gr. of mercuric chlorid, 1/100 gr. of sodium chlorid, and 1/160 gr. of carbolic acid. It can be given as high as 20 min., but usually 5 min., given daily, will give sufficiently rapid results. The carbolic acid readily controls the pain, and in a 5 min. injection the patient only receives 1/32 gr.

In choosing the site of the injection the post-trochanteric, he thinks, is most desirable. Several cases are reported.

36 The Therapeutic Uses of the Preparations of Benzoin. H. R. Coston.
37 *Cow's Milk Kumyss as a Nutrient in Disease. E. F. Brush.
38 Summer Complaints of Children. Samuel A. Visanska.
39 *Conservative Treatment of the Antrum of Highmore. Preston M. Hickey.
40 Poisoning by Camphor; History of Case; Recovery. Charles Stanley White.
41 *A Pharmacological Study of an Aseptic Preparation of Ergot Devised for Hypodermic and Internal Administration. E. M. Houghton.

34. **Paralysis Agitans.**—The treatment of paralysis agitans as suggested by Taylor is the use of carefully directed movements, passive and active, to overcome contractures and loosen the joints, education in voluntary movements, almost solely of the extensors in the arms and the flexors in the legs, but not neglecting other muscles. These should be instituted gradually. Great attention should be paid to the hands and feet. He sums up his treatment in that it consists in trying to overcome the growing apathy; to induce systematized return to normal activities; to use all gentle and yet forceful means to secure elasticity to the tissues, and finally, to stimulate the circulation in the spinal cord by graduated pressure on the spinal areas, thus restoring reflexly many of the fibers of the cord to function and improving others. Care and persistence on the part of the physician and the co-operation of the patient are essential. He does not prophesy a cure in these cases, but great improvement has been obtained in some very severe cases, warranting the hope that still better results can be obtained.

37. **Kumyss.**—Brush finds kumyss of special value in diseases of the digestive organs, such as catarrh, chronic diarrhea and in many cases of dyspepsia. It is the most grateful and useful food in continued fevers and in the convalescence from typhoid and pneumonia. In consumption it is invaluable, especially in the beginning stages. It is useful in chlorosis, anemia and prolonged lactation and all conditions of defective nutrition. He quotes the experience of other physicians as to its value in summer complaint of children and badly nourished cases. It is particularly useful in alcoholism and delirium tremens. The dose varies. The amount for the adult is the largest that can be taken without discomfort. In continued fevers the dose should be all that the patient requires for nourishment and to quench thirst. For infants the dose is correspondingly small, in some cases beginning with a teaspoonful.

39. **Antral Disease.**—Two cases are reported by Hickey, who offers the following conclusions: 1. Acute inflammation of the antrum when due to nasal infection should be treated conservatively for the first two weeks. 2. The constringing effect of adrenalin offers us a valuable and non-toxic agent in reducing swelling about the hiatus semilunaris. 3. When severe symptoms occur the proper position for favorable drainage from the natural outlet should be insisted on.

41. **Ergot.**—Houghton reports experiments made with ergot resulting in a new preparation which was made to obtain in solution as large a percentage of the sphacelinic acid and cornutin and other constituents of this type and rejecting as large an amount of the irritating and depressing principles as possible. This was produced by percolating through various media and throwing out by proper precipitants the undesirable constituents, checking the process by testing the filtrates and precipitates, giving them to roosters, observing the blackening of combs, etc., and the amount of irritation by hypodermic injections in guinea-pigs and studying the abortifacient effect on pregnant animals. The resulting product was a clear, transparent, light amber fluid representing one part by weight of the crude drug; of the same strength as the U. S. P. fluid extract. To act as a preservative a small quantity of chloretone was added, also for its local anesthetic properties. The substance thus produced is called ergone. He thinks it possesses the great advantage of being less toxic than the pharmacopeial preparation of ergot or Bonjean's extract. It is aseptic, non-irritating when given internally or subcutaneously, and physiologically active, at the same time being less toxic. Further clinical trial will be required to show its therapeutic value.

42 *The Treatment of Chronic Empyema. A. Primrose.
43 A Case of Tubercular Laryngeal Stenosis Treated by Tracheotomy. J. Price-Brown.
44 The X-Ray in Sarcoma, with Case. Charles R. Dickson.

42. **Chronic Empyema.**—Primrose reports cases treated by drainage and insists on the importance of this being as efficient as possible if much is to be gained by the procedure. He has not much faith in irrigation, and believes that it is liable to be dangerous. Many cases will be carried to a successful issue if drainage is maintained. He advises whenever pus is discovered in the pleural cavity to get rid of it in the early stage of the trouble by free drainage. Where this has had a fair trial and cure is not effected, Schede's operation of thorax resection should be undertaken if the general condition of the patient warrants it.

New Yorker Medicinische Monatschrift.

June.

45 *Typhus Abdominalis and Trinkwasser. A. Selbert.

45. **Water Supplies and Typhoid.**—Seibert's article is a study of the effect of filtration of water supplies on the occurrence of typhoid in various cities, which he illustrates by the graphic method in a very striking way. Especially is this marked in the case of some German cities like Hamburg, Hanover, Berlin and Breslau, where the sudden drop in the ratio of typhoid mortality is very remarkable. He concludes from his study that all lakes, rivers and brooks which exist in populated parts of the United States and Germany have been long infected with the typhoid bacillus, and that the chief carrier of the typhoid germ into the human body is the water supply of the town. All towns, therefore, which are compelled to depend on lakes, rivers and water courses for their water supply should avail themselves of the benefits of central sand filtration.

46 *Appendicitis: Ochsner's and Deaver's Methods Compared. W. J. Matthews.
47 Nephritis in Summer. William F. Waugh.
48 Experience vs. Theory. L. L. Loggins.

46. **Appendicitis.**—Matthews is a strong advocate of Ochsner's method of treating appendicitis, delaying operation if the attack has already lasted forty-eight hours, until all acute symptoms have disappeared for at least two weeks, and then removing the appendix. Under his system of rectal alimentation and stomach washing he thinks we are able to save even desperate cases. The statistics show well in its favor.

55 Illustration of the Circulation of the Uterus, Oviducts and Ovaries by the X-Ray and Bromide Method. Byron Robinson.
56 Hypertrophy of Tonsils. E. B. Hardin.

49. **Autointoxication in the Nervous System.**—The various autotoxins and autotoxemias are noted by Wyman, especially regarding their effect on nervous disorders. He finds as a result of his study that some autotoxin is an etiologic factor of very great importance in many functional nervous disorders, producing symptoms either by lessening, retarding, perverting or arresting the functional capacity of the nervous center, or by interference with the transmission of nerve impulses, involving both the central and peripheral neurons. Repeated and chronic autointoxication may lead to actual organic disease.

52. **Myoma of the Uterus.**—The 100 cases that are analyzed by Hunner occurred in the service of Dr. Howard A. Kelly during the former's term of eighteen months as resident gynecologist from Jan. 1, 1901, to April 1, 1902. Some of them are detailed. The following operations were performed: Myomectomy, 19; panhysteromyomectomy, 14; supravaginal hysterosalpingo-oöphoromyomectomy, 40; supravaginal hysteromyomectomy, leaving one or both ovaries, 16; vaginal myomectomy, 5; vaginal hysteromyomectomy, 6. Nine cases were treated by the method of bisection. There were 6 fatalities. In 5 of them the tumor was complicated by serious pelvic inflammatory disease. One died on the sixth day from septicemia; one on the third day from peritonitis, and one the fourth day from iliac vein thrombosis with embolism carried to the pulmonary artery; one died in ten hours from shock, which was noted before the operation; one and possibly two of the cases could have been saved if more time had been taken and the tumors removed by slow dissection. He says, while he does not undertake to draw conclusions, he thinks that if we meet in a brief record of 100 cases such a record of suffering, sterility, miscarriages, extrauterine pregnancy, hemorrhage, anemia, malignant growths, infections and deaths, one would not wonder as to his radical position as regards myoma. He does not say that he would operate in every case, but he thinks as our knowledge of the seriousness of the condition increases the indications for operating will expand.

57 *Inebriety a Disease. Lewis D. Mason.
58 *Are the Questions Relating to the Nature, Effects, Uses and Abuses of Alcohol as Existing in Fermented and Distilled Liquors Political Questions, to Be Settled by Votes at Ordinary Elections, or Are They True Questions Concerning the Public Health and Morals, and Therefore to Be Dealt with by the Sanitary Authorities and Courts of Justice? N. S. Davis.
59 Infantile Alcoholism. L. G. Robinovitch.
60 The Correlation of Alcoholism, Crime and Insanity. C. A. Drew.
61 Hyoscin in the Treatment of Morphinism. T. D. Crothers.
62 History of the International Anti-alcohol Congresses and the Temperance Movement on the European Continent. A. Forel.

57. **Inebriety a Disease.**—Mason pleads for the consideration of inebriety as a disease, not a vice, of the individual and its consideration on the same plan as insanity by the state and public.

58. **Alcohol and Public Health.**—Davis' article is a plea that alcohol should be treated as a poison, its use to be dealt with by the law as is the case with other poisons. He says the same methods of investigation applied to ether, morphin, cocain, etc., are fully credited and promptly acted on, but that in the case of alcohol the greed for pecuniary profits outweighs the regard for human welfare. As long as the contest can be kept in the field of politics these reasons will prevent anything more than temporary or partial success in the strife against alcohol. He does not say that the success in any case would be complete any more than it has been in regard to murder, theft, etc., but these occur less frequently than would be the case if laws for their direct suppression were not in force, instead of their regulation by licensing persons to do all the killing, stealing, etc., on payment of a certain amount to the public funds.

Buffalo Medical Journal.

August.

63 Some Curiosities of Medical Practice. Chauncey P. Smith.
64 *A Theoretical Note on the Vital and Toxic Theories of Cancer, and Their Bearing on the Parasitic Theory. G. H. A. Clowes.
65 *The Medical and Surgical Treatment of Bright's Disease. Charles S. Jewett.
66 Clinical Notes on Dysemia. Louis J. Gravel.

64. **Cancer.**—The theories of cancer are reviewed by Clowes, who attempts to show that the parasitic theory is not in any sense incompatible with various toxic or chemical theories, and that the production of the toxins generally recognized as playing an important part in this disease may be most readily attributed to some form of intracellular parasite. This explains the constant stimulation of cancer cells and the selective action of the toxins for one particular cell to the exclusion of others, and the apparent impossibility of infecting healthy individuals with cancer blood.

65. **Bright's Disease.**—The various treatments of Bright's disease, especially the surgical treatment suggested by Edebohls, are noted by Jewett, who offers the following tentative conclusions:

1. In certain cases of acute nephritis operation may be of use in relieving suppression of urine, pain, or hematuria; it may, perhaps, hasten recovery and aid in the prevention of chronic nephritis.
2. In hopeless cases of chronic nephritis, decapsulation will sometimes relieve distressing symptoms and prolong life.
3. Should the results claimed by Edebohls be duplicated in the practice of various operators, and should the supposed reparative results of his operation be confirmed by future autopsies, then the possibility of operative cure of certain cases of chronic nephritis must be admitted.

Maryland Medical Journal, Baltimore.

August.

67 The Origin, Purpose and Working Methods of the Medical Milk Commission. Henry L. Coit.
68 *The Use of Antitoxin in Diphtheria Associated with Pregnancy. J. Elmond Kempter.
69 *Two Minor Communications from the Clinical Laboratory. Thomas R. Brown.

68. **Antitoxin in Pregnancy.**—Kempter reports a case of diphtheria in a woman eight months pregnant which was treated by antitoxin with the usual good results. He thinks this is the first case recorded in which antitoxin was used during pregnancy and a healthy child was born at term. He suggests the possibility of production of immunity in a child by the use of antitoxin in the mother.

69. **Salt Solution Enemata and Leucocyte Counting.**—Brown suggests the value of salt solution enemata, especially after renal operations, on account of their diuretic effect and reports experiments. As a result of these it has been the custom in Dr. Kelly's private hospital to use the following method in all cases where the kidney has been operated on: A pint or more of normal salt solution is administered by rectum every six, eight or twelve hours, according to the needs of the case, for a number of days after the operation. This has caused in 6 cases of nephrotomy and 12 or more of nephropexy in which the plan has been adopted a very free secretion of urine. Convalescence has been more comfortable and nausea and headache markedly diminished. The method is so simple and so easily carried out that he thinks it should be incorporated among the general procedures in the after-treatment of all cases operated on under general anesthesia.

In the same article he reports a number of cases of appendicitis in which the leucocyte count was used, illustrating its value as distinguishing cases of peritonitis, autointoxication, constipation, hyperchlorhydria and intestinal obstruction. Peritonitis is always accompanied with leucocytosis, excepting in intense infections, and intestinal obstruction is associated with it when inflammatory processes or beginning gangrene exist. Autointoxication with constipation and intense hyperchlorhydria are not associated with the leucocyte increase, and are to be treated on medical not surgical lines, hence the absence of leucocytosis may be of real value in distinguishing whether or not post-operative surgical interference is advisable, especially in anemic patients or those with an atonic condition of the gastrointestinal tract or those in whom the intestines had been handled a great deal. The leucocytosis of infection must not, of course, be confused with the transient post-anesthetic leucocytosis, especially if ether has been employed. He reports the conclusions of King on post-operative non-septic leucocytosis, noticed in THE JOURNAL, xxxix, ¶49, p. 723.

Titles marked with an asterisk (*) are abstracted below. Clinical lectures, single case reports and trials of new drugs and artificial foods are omitted unless of exceptional general interest.

British Medical Journal, London.

August 8.

1 A Discussion on the Vaccination Acts and the Prevention of Smallpox. J. C. McVail.

2 The Midwives' Act of 1902. J. Ward Cousins.
3 *The Spread of Enteric Fever and Other Forms of Illness by Sewage-polluted Shellfish. Arthur Newsholme.
4 *River and Seashore Pollution as It Affects Shellfish. (To be continued.) J. T. C. Nash.

3. **Shellfish Infection.**—Newsholme notices the more recent outbreaks of typhoid, etc., attributed to shellfish, and reviews the evidences. The clinical evidence is supported by the ability to exclude other known causes and the topographical evidence by tracing the molluscs to their original layings and the changes that have been made. The bacterial and chemical evidence is of last and least importance. He suggests legislative regulation and control of the supply and the sale of these articles of food.

4. **Shellfish Pollution.**—Nash takes up the same subject and points out how the purification of sewage may extend the dangers.

12 A Note on Colotomy and Colectomy. F. T. Paul.
13 *Can the Respirable Products of Human Waste Hinder Development and Lower Vitality? John Hartley.
14 *Ichthyol in the Treatment of Pulmonary Disease. James Burnet.

5. **Tuberculosis.**—Bulstrode in this third lecture reviews the sanitarium system and the laws as regards notification in different countries, putting Germany at the head of the rank in its efforts of combating tuberculosis. He says if the compulsory notification of tuberculosis implies all the discomforts usual with the notification of contagious diseases, it would be improper. The only way is to have consumption in a special category by itself. He thinks in this case there will be no great difficulty in obligatory notification. He doubts, however, whether it is advisable to include other than pulmonary cases under this rule. Another important matter would be the preparation of facilities for bacteriologic examinations, still others, the education and examination of school children, the control of expectoration, etc. He does not have full confidence in resort to the sanatorium movement. As a curative agent these institutions are almost indispensable and in prevention they largely curtail the prevalence of the disease by education, but there is still a large margin of danger in the patients that leave these institutions. The mere isolation of early cases in a sanatorium is not a panacea.

6. **Insanity.**—Jones points out how the stress of modern civilization and the tendency to urban concentration has increased insanity. While the present system of education has raised the general intelligence, it has destroyed the individuality to a large extent. Altruism is lessening. The well-to-do classes are more self-indulgent, and as to the improvement of the workingman's condition he thinks it has drawbacks as well as advantages. Higher wages seem only to increase discontent and the socialist tendency is one leveling down and crushing individual attempts to rise. He thinks that alcoholism in women is increasing. With the progress of civilization he says insanity is not only on the increase, but the occurring varieties are less curable. The physique of the urban population has deteriorated. The statistics of recovery are less favorable today than they were twenty-five years ago. Serious as the case may be we can not hope for or expect relief from the great financial and economic burden of providing accommodation for the insane in the future. If relief is to come it will be in some great change affecting the physical as well as the mental health of the masses of the people.

13. **Bad Air.**—The evil effects of vitiated atmosphere are insisted on by Hartley, who thinks that the respiratory products of human waste in the atmosphere go a long way to injure the public health. The idea of the perfect wholesomeness of atmosphere is, he thinks, possibly a mistake. We flood our rivers and pollute the sands of our health resorts with the sewage and we ventilate our sewers in narrow streets and alleys at the road level, and as to our sleeping rooms, most of us do not ventilate them at all in clearing out waste products. He says one is led to question whether the ills usually ascribed to the high pressure of modern civilization may not be more justly laid to the toxins given off by our crowded population.

14. **Ichthyol in Tuberculosis.**—The value of ichthyol in the treatment of tuberculosis is described by Burnett, who gives his experience. He does not claim to have cured his cases, which were 13 in number, all of the ordinary slow progressive type. Eleven were distinctly improved. Only 2 failed to show any beneficial results, and these were of the advanced type with both lungs extensively involved. The first sign of improvement was in the cough, improvement in sleep and lessening of expectoration followed. Gain in weight was not observed until the patients had been under treatment for a considerable period, but in every case there was marked nutritional improvement and food was taken with greater relish. All the gastric discomforts previously present had left. Age did not seem to count much in the treatment by this method. The amount given was 8 to 20 grains four times a day; he gave it in capsules containing 4 grains, and in every case he started with 2 capsules four times a day and increased the amount until five were taken at each dose. This seems a large amount, but is tolerated when the drug is taken in this way. He does not consider that it acts as an antiseptic to any great extent, but it has a direct effect on general nutrition, acts as a vasoconstrictor and relieves and removes congestion and inflammation. His firm conviction is that it is a distinct anti-inflammatory agent, but is also to some extent an antispasmodic. He finds it absolutely free from irritating properties so far as the stomach is concerned.

23 Cases with Comments. A Case of Threatened Puerperal Eclampsia, Edward Ellis. A Case of Double Hare Lip, with Absence of Nasal Septum, S. Davidson.
24 Enteric Fever and Infected Blankets. Louis C. Parkes.

16. **Metabolism in Gout.**—An analysis of the case reported by Futcher suggests, he says, the close parallel relation between uric acid and phosphoric acid excretion in gout, and favors the view that both are products of nuclein disintegration. In the quiescent intervals both phosphoric acid and uric acid are markedly reduced below normal. Two or three days after the acute arthritic symptoms commence the phosphoric acid and uric acid gradually increase until they reach the average normal output, or even its upper limit and fall again as the acute manifestations subside.

17. **Tuberculosis in Children.**—The point chiefly made by Price-Jones is that alimentary tuberculosis, so-called, is not necessarily from the ingestion of milk, but more probably from human tuberculous bacilli. He thinks it would be advisable to have bacilli causing alimentary tuberculosis isolated and studied to determine whether they are always the same organism and what relation they bear to organisms found in milk from cows with tuberculous udders and to other so-called varieties of tubercle bacilli.

Journal of Tropical Medicine, London.

August 1.

25 *Notes on the Genus Stegomyia (Theobald) and Its Distribution. F. V. Theobald.

25. **Stegomyia.**—Theobald describes the genus *Stegomyia* and its various species with their distribution, pointing out the characteristic features of *Stegomyia fasciata*, which is the most important of the species owing to its wide distribution and abundance. Only three species may be said to be abundant: *notoscripta*, which is common in parts of Australia; *scutellaris*, abundant in India, the Malay states, China, Japan, etc., and *fasciata*, probably originally an American species, but spread almost all over the world. There is only one other species, *sugens*, that is at all widely distributed, and that is rare. He thinks it probable that the two next abundant species after the fasciata may also, under favorable conditions, become transmitters of the yellow fever germ and carriers of the disease.

43 Askaris im Ductus choledochus. Choledochotomie. Neugebauer.

26. **Sixty Subphrenic Abscesses.**—Körte regards the pleural mode of intervention, with resection of ribs, as the best means of operative treatment of a subphrenic abscess. It affords better facilities for drainage, especially if the pleura is already infected. In case it is not infected the costal pleura may be sutured to the diaphragmatic pleura with a Volkmann suture, as he has done in 14 cases. Infection followed in only 4. He operated by the pleural route in 41 of his 60 cases. In 19 he opened the abscess from below, either from the front, side or lumbar region. In 27 the abscess proceeded from the appendix, in 9 from the stomach, in 2 from the biliary passages, in 4 from the pleura, in 1 from the pancreas, in 5 from the spleen, in 3 from echinococcus cysts in the liver, in 2 from a rib, and in 4 from the kidney. Of the total 60 cases only 40 recovered. He reviews the particulars in detail.

27. **Pneumococcus Peritonitis.**—Jensen announces that his numerous experiments on guinea-pigs inoculated in the abdomen with pneumococci have established that neither phagocytosis nor the bactericidal properties of the serum are the principal means of defense against pneumococcus invasion of the abdomen. Absorption is the main reliance of the organism. He found pneumococci in the blood in four minutes after they had been introduced into the peritoneum. Resistance to peritoneal infection is, therefore, the task of the general circulation, in which the entire organism shares. He reviews 20 cases from his own practice and 86 he has found in the literature, with 134 articles on the subject. His conclusions are that the peritoneum is most frequently infected with pneumococci from the intestines. He discovered these germs in the feces in several instances. A simultaneous or preceding pneumonia was only exceptionally noted. In children pneumococcus peritonitis is usually of the circumscribed, favorable variety, but in adults the diffuse form prevails and a concomitant pneumonic process is more frequently noted.

28. **Operations for Urinary Calculi.**—Dsirne has performed sectio alta in 106 and sectio mediana in 186 cases in the last eight years. The mortality has been 95 per cent. in the former and 1.6 per cent. with the latter. In after-treatment it is very important to keep the urine acid, and this he accomplishes by administering sodium salicylate and salol. If the urine is normal he sutures at once; if not, he inserts a permanent catheter, unless the patient is a young child. With much altered urine he drains the bladder through the perineal wound. He rejects sectio mediana for small children as it is impossible to work through the bladder outlet without injuring it, as also in case of stones too large to be extracted in this way.

29. **Tuberculous Peritonitis.**—Friedländer rather scoffs at the idea that laparotomy has a curative action in this affection. Many cases recover spontaneously, and a laparotomy may be useful to remove a stagnating exudate after the inflammation has subsided, and also to evacuate a pus pocket. To prevent a subsequent fistula adhesions should be spared as far as possible.

35. **Dry Asepsis Versus Moist Antisepsis.**—This communication from v. Bergmann's clinic is valuable testimony in favor of dry asepsis. For treatment of accidental wounds dry iodoform gauze deserves the preference, as it absorbs blood and secretions while at the same time having a destructive action on bacteria. The number of germs diminished much more rapidly in suppurating wounds under dry than under moist dressings. Many accidental wounds with large quantities of germs heal with no symptoms of inflammation.

36. **Surgery of Blood Vessels.**—From the same clinic extensive experiments on dogs are reported, undertaken to test the value of Payr's absorbable magnesium prothesis. The results were all favorable when the artery was over 3 mm. in diameter. Smaller than this the experiments always resulted in thrombosis. Höpfner commends the prothesis for injuries of large vessels in which more than one-half of the circumference is involved. He also reports successful transplantation of the carotid artery into the femoral, and *vice versa*, on the same animal and from dog to dog. Attempts to transplant a vein into an artery always resulted in aneurismal dilation of the vein and thrombosis. Experiments with transplantation of vessels from one species into another also all failed. He reports further that an amputated hind leg was sutured into place again, the artery united by a circular suture. In 2 dogs gangrene followed, but in a third the animal survived, succumbing the eleventh day to chloroform.

37. **Technic of Osteoplastic Amputation.**—The flap of bone and periosteum in an amputation according to Bier frequently sloughs off. Frommer thinks that if the skin is included in the flap the better nutrition ensures better results. He describes 30 cases thus treated, with faultless stumps.

39. **Collargol in Anthrax.**—Baracz reports 3 severe cases of anthrax that yielded with surprising promptness and completeness to intravenous injection of collargol. Experimental anthrax in rabbits, however, did not seem to be modified by this treatment. He attributes this inefficacy to the smallness of the doses, and insists that larger amounts can be administered than those hitherto employed. He tested on dogs all the other preparations of colloid silver, concluding that collargol is of them all the most harmless and the most effectual. No by-effects were observed except the inevitable chill.

40. **Retrograde Intubation.**—Busalla describes 3 cases of granuloma formation or protrusion of the tracheal wall, preventing the discarding of the tracheal tube. He succeeded in inducing atrophy of the granuloma, etc., by adopting v. Cackovic's method of retrograde intubation, that is, inserting a rubber drain, 4 cm. long, through the tracheal wound, one

end passing into the trachea, the other end into the larynx, and held in place by a silk thread tied around the middle of the drain and fastened to the neck.

44. **Tier Suture of Abdominal Wall.**—Werth has examined lately 393 patients out of his total of 1,338 laparotomies. In 279 the operation had been performed from one to fifteen years previously. Hernia had followed in 13 of the 393, but in only 5 was it a cicatricial hernia, and in these cases there had been suppuration of the laparotomy wound. He always uses "cumol catgut" and keeps his needles in pure lysol. In 19 cases no adhesions were found at a second laparotomy, while in 17 they were noted.

46. **Tampon Drainage After Laparotomies.**—Döderlein has drained through the posterior vaginal vault 161 times in 754 laparotomies, draining through the abdominal incision in only 12. His operative mortality was 3.7 per cent. The mortality in 593 cases not drained was 2.3 per cent., and of the others 8.7 per cent., the difference due to the severity of the lesions. The most unfavorable results were observed with suppurative processes.

47. **Drainage After Laparotomy.**—Fehling prefers abdominal drainage, and resorts to the vaginal only after a Werthheim operation or colpotomy. He drains by Mikulicz's technic, and reports that he used it in 36 out of 327 laparotomies, his total mortality being 4.5 per cent.

56 Leukocytæmi og Appendicitis. E. Müller.

50. **Laryngeal Tuberculosis in Pregnancy.**—Godskesen reviews 55 cases, only 24 of which have been previously published, and analyzes his own material, which is included. On the basis of these experiences he formulates the principles for procedure as induction of abortion in the early months of the pregnancy, and later, careful supervision with tracheotomy at the right moment. The dangers of pregnancy in case of laryngeal tuberculosis are shown in the series of 31 previously unpublished cases which he has collected, including 1 reported by V. Pleth of Chicago. The death of the mother soon after delivery is mentioned in all but 5 or 6, and in only 7 did the child survive. The pregnancy ran its course to term in 25 out of 46 cases. In 26 the child was delivered alive, and in 23 instances it proved to be healthy. The patients died undelivered in 3 cases and abortion occurred in 5. In 8 delivery took place four to six weeks before term, in 2 of these artificially induced. The insidious beginnings of laryngeal tuberculosis and its rapid development under the influence of pregnancy should rouse the physician to be on the alert at the slightest symptoms attracting attention to the throat, especially in patients who have apparently recovered from a tuberculous throat or lung lesion. In 26 cases the laryngeal tuberculosis commenced during the pregnancy usually during the first half. In 7 cases the affection had existed prior to the pregnancy, but had caused no alarming symptoms until then, and in the others the pregnancy did not seem to materially affect the lesion in the throat. The lungs were involved in nearly all the cases, but the throat lesion was predominant. In 35 local treatment or an endolaryngeal operation was alone attempted. In 2 a tuberculous circumscribed tumor was successfully removed. Tracheotomy was done in 8, laryngo-fissure in 3 and subhyoid pharyngotomy in 1. The tracheotomized patients were in the fifth or sixth month one each, and 2 each in the seventh, eighth or ninth month of the pregnancy. Three died soon after the abortion or delivery; 2 were dismissed in comparatively good health after delivery; 2 died nearly two years later from the progress of their tuberculosis and one is still alive after eight years. These results are encouraging, as this operation is undertaken only in the severer cases. There is no doubt but what more of the children might have been saved if tracheotomy had been done more frequently.

51. **"Side Adenoids."**—In 200 operations for adenoids undertaken at Mygind's clinic during the last year, the vegetations were what he calls "side adenoids" in 9 cases. In his private practice the number was 11 in 120. Some of the patients were 30 to 40 years old. The symptoms seem to be about the same as with the ordinary vegetations. He gives cuts of a couple of adenotomes especially adapted for reaching these "side adenoids." They seem to resist the tendency to atrophy more than ordinary vegetations.

52. **Experimental Cancer Research.**—Jensen has continued his studies of malignant tumors on white mice and now announces that he has succeeded in transmitting through 22 generations a tumor growth originally derived from cells of a melano-sarcoma on a horse. He gives photogravures of one of the mice showing the external aspect and the dried specimen of one of the tumors, which swelled the animal to nearly twice the normal circumference of the body back of the front legs. He also gives 14 cuts of the histologic findings. They indicate a pronounced carcinomatous structure, but there was no evidence of metastasis. The tumors continued to grow until the animals died from cachexia or from ulceration of the testicles. The tumors were transmitted from one generation to another by transplantation, and the transplantation was successful in 40 to 50 per cent. of all the attempts on white mice, but failed on other animals except on a few ordinary mice. There was not the slightest evidence in favor of a parasitic action.

54. **Treatment of Lupus with Refrigeration.**—Sorensen reports that he has treated 6 cases of lupus to date with a freezing application, spraying the parts with ethyl chlorid, as practiced by Detlefsen. Such remarkable improvement was obtained that he thinks we can rank the Detlefsen with the Finsen method of treating lupus as a notable progress. He regards the Finsen as the standard method, but in cases in which a course of Finsen treatment is impracticable, the freezing method enters on its rights. It is peculiarly adapted for private practice. The sittings are daily at first, then with longer intervals.

57. **Traumatic Injuries of Meniscus.**—Bovin has found in the literature reports of 163 cases of total or partial extirpation of the meniscus on account of traumatism. He tabulates the details of 148 of them; all but 26 were cases of rupture. He further gives the complete history of 10 cases he has personally observed and treated. He also gives his conclusions in regard to the physiology and anatomy of the meniscus from the study of 15 fresh and 36 formalin-hardened specimens. He affirms that

the meniscus is not a rigid and unyielding body, but changes its shape and position under the influence of traction and pressure. Twelve photogravures accompany the comprehensive article. The median meniscus is found injured much more frequently than the lateral, and isolated rupture of the capsular insertion was the most frequent of all. A recent injury of the meniscus is often mistaken for an internal sprain or contusion with hemarthrosis or for acute traumatic synovitis. An old injury may be mistaken for a free or pedunculated body in the joint or other lesion. The slightest suspicion of recent injury of the meniscus imposes the necessity of immobilization and bed rest for three or four weeks after the dislocated cartilage has been replaced. In chronic cases an operation will usually restore normal function to the joint. An old injury of the meniscus left to itself is liable to seriously compromise the function and entail chronic synovitis, and possibly arthritis deformans. The meniscus was sutured in 39 cases, and in 6 there was recurrence. Infection and ankylosis occurred in 2 and protracted convalescence in 1. The longer manipulations required for suture increase the probabilities of infection. Effusion requiring tapping a few times followed in one case. In 2 others the movements of the joint were somewhat restricted, probably from the longer mobilization required after suturing than after extirpation. Bovin resorted to suture only once. This was a case of recurrence of the disturbances after partial resection. The fragment of the meniscus that had been left was sutured to the capsule with perfectly satisfactory results.

58. **Diagnosis of Lung Affections.**—Hedenius warns that we must not rely too much on the physical signs in diagnosing tuberculosis. He mentions that the muscle sounds in the esophagus are liable to deceptively simulate râles, and describes a case in which the physical signs indicated apical catarrh, and a "congestion bronchitis" was found localized in the apex, but no traces of tuberculosis could be detected. Death had occurred in consequence of heart disease, and special care is necessary in determining the significance of the physical signs in the lungs in case of heart disease or with emphysema or curvature of the spine. In another case he describes the *Streptococcus longus conglomeratus* was apparently alone responsible for the symptoms and lesions, bronchopneumonia with multiple abscess in the lungs, diffuse sero-fibrinous pneumonia and empyema at three points in the wall of the thorax, suggesting actinomycotic infection. An abscess was also found in the thalamus opticus.

60. **Saline Infusion in Acute Anemia.**—In this second part of Zachrisson's study he reviews 20 cases he has found on record in which saline infusion proved a life-saving measure in acute anemia. He comments with surprise on the fact that all but 2 were published by American or English writers, and also on the invariable success of the measure. The unsuccessful cases are probably not published, he adds. He reviewed 7 cases from his own experience in the first part of his article.

62. **Reducing Power of the Urine in Diagnosis.**—Lucatello tabulates the fluctuations in the reducing power of the urine in different diseases, and urges wider use of this simple approximative test of the elimination of the extractives. He illustrates the Bufalini apparatus for the purpose, which is a modification of Gerhard's.

63. **Auto-Hemolysis from Alcohol.**—Mircoli noticed in a certain hard drinker that sudden suspension of liquor was followed by hemoglobinuria, which vanished at once when the man resumed his alcohol. Tests on some rabbits also showed that the serum was blood-stained after ingestion of a small amount of alcohol daily for three months. There was no hemoglobinuria, but the proportion of urobilin was abnormally high. He thinks that the alcohol causes hemolysis, but that the rabbit kidney, being comparatively healthy and vigorous, transforms the bilirubin into urobilin. This occurred also in the hard drinker first mentioned, except when his exhausted and probably pathologic kidney missed the accustomed stimulus of its daily quantum of alcohol. The rabbit blood under the influence of the alcohol also lost its coagulating power almost entirely. These effects of the alcohol on the blood are not direct, as *in vitro* it does not dissolve the reds nor prevent coagulation. They suggest that alcohol should be avoided when there is a tendency to hemophilia.

65. **Antipneumonia Serum.**—Tizzoni's serum is derived from rabbits, and he has had only a small quantity at his disposal. The results of its application in 7 clinical cases are described in detail. It was given by intravenous injection and never produced the slightest inconveniences of any kind. The smallness of the dose prevented any disturbance of the circulation. His subjects were from 14 to 42 years old, and the injections were commenced the second to the fifth day of the disease. In three patients there were malarial antecedents. The beneficent action of the serum was unmistakable, rendering the entire syndrome milder, the expectoration looser. The softening effect on the sputa and its easier expulsion resemble the effect of antidiphtheria serum on the false membranes. All of the patients injected before the fifth day showed marked benefit, but one not treated until the fifth to seventh days did not seem to be affected.

67. **Causes of Sudden Death in Infants.**—Segadelli argues to prove that reflex inhibition from a mild gastro-intestinal catarrh may be a cause of sudden death in an infant, and describes a case which he thinks belongs in this category. The catarrhal affection had been so slight that it had failed to attract attention and was revealed only at the autopsy.

68. **Iodized Milk in Pyemia.**—Professor Sclavo of Siena prepares an iodized milk by adding iodin and albumin to milk freed of its fat, and sterilized. It can be administered by the mouth or by subcutaneous injection, and has proved a remarkably effectual means of giving iodin, especially in local tuberculosis, exophthalmic goiter, digestive disturbances, etc. The Italians attribute to iodin the property of augmenting the organic resisting powers, enabling the tissues around a local lesion to maintain a more effectual defense. Sotis states that Sclavo's iodized milk promptly benefited 2 patients with chondroperichondritis and 1 with laryngeal stenosis, in the latter case rendering the projected tracheotomy unnecessary. It also aided in the cure of 2 cases of chronic suppuration of the ear, and Ferreri reports great advantage from it in sclerosis of the middle ear, syphilitic or otherwise. Other examples of the benefits from iodized milk in intoxication from an acute or chronic infection are being constantly reported, and Santoro here describes 2 cases of pyemia in which

the patients completely recovered after a daily injection of 10 c.c. of the iodized milk for 24 to 50 days.

69. **Surgical Treatment of Medical Nephritis.**—D. Maragliano reviews the work that has been done in this line, and prophesies a brilliant future for the operation of nephrolysis as possibly equally effective while much less serious than nephrotomy. He adds that no clinical experiences with it have yet been published.

71. **Guaiacol in Mumps.**—Grande has reported great relief from inunctions of the inflamed glands with a salve of 1 gm. guaiacol to 10 gm. each of vaselin and lanolin. Ragazzi corroborates the prompt benefit from its use; the pain subsides and the general symptoms become rapidly attenuated.

77. **Suture of Arteries.**—Salomoni mentions that Matas' method of suturing arterics closely resembles the method he reported in 1900 after long experimental testing. He aims to bring the endothelium on both stumps into extensive contact, passing the needle from without into the vessel on one lip, and from within outward on the other.

78. **Serum Treatment of Pulmonary Tuberculosis.**—Piera has used the Maragliano serum extensively, and states that his and others' experience has shown that serum treatment will cure all the cases of circumscribed tuberculosis, without cavities, and with or without fever. Also the diffuse forms of superficial inflammation, even although apparently very severe. The diffuse forms with infiltration are also curable under prolonged treatment, but the forms with cavities are not curable by this means.

80. **Physio-Pathology of the Pancreas.**—De Domenicis concludes his monograph with the statement that the destruction and elaboration of sugar may occur independently of the pancreas, indicating that other organs participate in these processes. Total destruction of the pancreas entails severe disturbances in the metabolism owing to the loss of this important factor in the processes of digestion. The liver suffers particularly from its loss, and secondarily the nervous system.

81. **Diagnosis of Incipient Tuberculosis.**—Ceraulo calls attention to the frequency of palpitations and of phosphaturia in commencing tuberculosis. He noted the former in 7 out of 11 cases, and the latter in 9. He did not find enlargement of the glands in the axilla as constant as these other signs.

82. **Tuberculosis Cured by Intercurrent Infection.**—Silvestri describes 3 cases which he thinks justify him in the assumption that a secondary streptococcus invasion of the lungs following a recently-established tuberculosis, rendered the tissues unfavorable for the tubercle bacilli. The consequence was that the latter died out, and when the patients had recovered from their streptococcus infection the tuberculosis was extinguished.

84. **Isolation, Bed-Rest and Psycho-Therapy for Neurasthenia, Etc.**—Arnaud lauds in high terms what he calls "Déjerine's modification of the Weir-Mitchell treatment." He has coined the term "clinopsychotherapy" for it and relates numerous instances to prove its value, even in a public hospital, for treatment of hysteria, neurasthenia and allied conditions. The psychotherapy is the most important feature, and its influence is amazingly enhanced by the other measures, as has been proven in 200 cases thus treated at the Salpetrière Hospital at Paris.

87. **Patent Foods After Surgical Operations.**—After operations on the gastrointestinal tract the question of feeding is of great importance. Vermel is convinced that the artificial foods on the market, such as somatose, sanatogen, tropon, etc., are useful only when given in combination with fats and carbohydrates, as they consist mainly of albumin. The patients are unable sometimes to tolerate them in large quantities, and small amounts fail to supply the necessary quota of calories. He prefers the ordinary articles of diet, milk, cream, eggs, alcohol, meat juice, sugar, etc., in the right proportions to supply the needed fat, albumin and carbohydrates. This method in his clinic has given the best results.

88. **Treatment of Associated Syphilis and Tuberculosis.**—The differential diagnosis between syphilis of the lungs and pulmonary tuberculosis is difficult, but differentiation is liable to be still more difficult when the two diseases are associated. Opinions differ as to treatment of this combination of syphilis and tuberculosis. Zakharin, Hiller and others believe that antisyphilitic treatment is dangerous in this case, but Neisser, Potain, Pospeloff and others advocate it. Langovoi reports 2 cases which prove the correctness of the latter view. The first patient was a man of 47 who contracted syphilis at 22 and tuberculosis of the lungs at 44. He was treated with potassium iodid—20 to 30 grains daily for two weeks with thirty inunctions of gray ointment, 45 grains daily, and after twenty-five days five inunctions of 60 grains each and then seven of 80. The general condition and all the symptoms improved under this treatment. The red corpuscles increased from 4,220,000 to 5,800,000 and the hemoglobin from 70 or 75 per cent. to 85 and 90 per cent. The cough and dyspnea subsided, but the tubercle bacilli were still found in the sputa. The antisyphilitic treatment had evidently done no harm and had much benefited the patient. The second patient was a man of 33, who entered the clinic on account of complete aphonia. The laryngoscope disclosed an ulcer on the right vocal cord assumed by one specialist to be of a tuberculous nature, while another diagnosed it as syphilitic. There was a history of syphilis contracted twelve years previously, and followed four years later by slight hemoptysis suggesting tuberculous infection of the lung. Symptoms of tabes dorsalis were also apparent on careful examination. The treatment consisted in inunctions of mercurial ointment of 50 to 80 grains each for fourteen days, with potassium iodid at the same time, 20 to 30 grains a day. All treatment was then suspended for two weeks, after which the inunctions were resumed, 80 grains daily, with potassium iodid internally for eighteen days. Examination of the larynx then showed the complete cicatrization of the ulcer, while the voice had returned to normal, and all traces of the tabetic symptoms had vanished. It was assumed that the patient had presented a syphilitic polyneuritis and meningitis, which induced compression of the nerve roots and this had been the cause of the tabetic symptoms. As the polyneuritis and meningitis improved under the antisyphilitic treatment the symptoms subsided.

91. **Treatment of Cancer in Pregnant Uterus.**—Uspensky has found that cancer in a pregnant uterus is especially

liable to involve early the pelvic glands, and, hence, prompt and radical surgical intervention is particularly necessary in such cases. The complication with pregnancy does not modify the indications. Vaginal extirpation is preferable, he thinks, and can be done up to the third or fifth month without reducing the size of the uterus. Up to the fifth or seventh month evacuation of the liquor amnii is usually sufficient for the purpose, but later than this the fetus must be extracted. If viable, vaginal cesarean section is indicated, followed by total extirpation of the uterus.

94. **Unusual Forms of Tabes.**—Lapinsky, in 5 cases, noted paralyses or pareses of the arms or legs as the initial symptoms of tabes, before sensory disturbances developed.

95. **Antistreptococcic Serum in Chorea.**—A girl of 18 exhibited a violent form of chorea minor, accompanied by retention of urine, temporary paralysis, aphasia and mental disturbances. As arsenic, chloral and bromids failed to relieve, and as streptococci were found numerous in the blood, treatment with antistreptococcic serum was attempted. After thirteen to fifteen injections the symptoms abated and the patient recovered. A slight relapse was cured by Fowler's solution. The marked benefit from serum treatment in this case suggests that chorea minor may in some cases be due to infection and that the blood should be examined as a routine measure and polyvalent antistreptococcic serum used in appropriate cases.

96. **Nervous-Cerebral Forms of Grippe.**—The action of the grippal toxin on the brain substance is liable to induce intermittent fever and also pulsus tardus from its influence on the vagus center. These two symptoms are characteristic of la grippe, Velyamovitch believes, and reports a case to confirm this opinion.

97. **Operative Treatment of Cancer of the Pylorus.**—Rose urges prompt operation and reports two cases. In the first the patient was still in good health fifteen months after resection of the pylorus, rapidly recovering after the operation. In the second case gastroenterostomy was performed and the symptoms were relieved for fifteen months, after which slight evidences of recurrence of trouble were manifest. Free hydrochloric acid appeared in the stomach contents after intervention in both cases, and the lactic acid disappeared.

98. **Cholelithiasis.**—In one of the 3 cases described, the gallstones had developed under the influence of malaria, the parasite being found in the blood, and all symptoms vanished under quinin sulphate, 9 grains a day, supplemented by Fowler's solution. In another case the gallstone affection had lasted unrecognized for fifteen years, until the patient evacuated 3 gallstones in the feces and 146 more in the twenty following days, all without colics. A fistula had evidently formed between the gall bladder and duodenum. The patient had no further disturbances. About three weeks before voiding the stones the patient had taken six calomel powders of 2.75 grains each in the course of a day, and this had been followed by a mild course of specific treatment, as syphilitic antecedents were suspected. Five leeches and some Spanish flies had been also applied to the gall-bladder region. In cases in which small stones are suspected surgical intervention should not be considered unless medical treatment fails to produce good results soon. The differentiation is the chief difficulty.

99. **Pathology of Broad Ligaments.**—Lvoff reports 2 cases of fibroma of the broad ligaments, the surrounding organs intact, and 2 of echinococcus cysts in these ligaments. All were treated by extirpation of the affected ligament, with most satisfactory results. The ligament and fibroma in one case were removed through a posterior colpotomy, in another through a lateral colpotomy on the corresponding side. The echinococcus cysts were removed by a laparotomy in one case, supplemented in the other by posterior colpotomy on account of a concomitant parametritis.

100. **Cerebral Syphilis.**—In the 2 cases described mercurial and iodid treatment, supplemented by local blood-letting (Spanish flies to the neck) produced great improvement. In each case there were marked disturbances in the memory. This symptom is characteristic of Korsakoff's psychosis. Muravieff believes that it indicates a syphilitic affection of the brain.

102. **Value of Mineral Waters in Cholelithiasis.**—Radkevicz is convinced that mineral waters are fully as important as operative treatment for the cure of cholelithiasis. Surgical intervention does not exclude the possibility of relapses, but followed by treatment with mineral waters, it ensures a complete cure.

New Patents.

Patents of interest to physicians, July 21-August 11:

735660. Formaldehyde fumigator. Leon Feval, New Brunswick, N. J.
735670. Stethoscope holder. William Jones, Denver.
735276. Vaginal syringe. John R. Lane, New York City.
735542. Spirometer. Henry T. Lyttleton, Marshall, Texas.
735396. Machine for grading tablets. James M. MacDonald, Detroit.
735400. Surgical instrument. Richard P. McCully, Brooklyn.
735135. Invalid bed. William McLennan, Ogdensburg, N. Y.
735141. Surgical apparatus. George A. Ogle, Catonsville, Md.
735581. Therapeutic apparatus. Adrian Pollacsek and B. Beer, Vienna.
735591. Depurator. Lloyd H. Richards, El Paso, Texas.
735325. Hernial truss. Carl Weck and F. Weck, Grafrath, Germany.
735687. Electrotherapeutic apparatus. Scheuyler B. Zink, Portsmouth, Va.
735851. Therapeutic apparatus. Gerald L. Abell, Oakland, Cal.
736059. Device for administering anesthetics. George L. Bennett, Chicago.
736072. Arm rest for crutches. Harry S. Cole, Newtonsville, Ohio.
735860. Device for preventing flat feet. Catharine L. Darby, Brooklyn.
735723. Nebulizer. Thomas De Vilbiss, Toledo, Ohio.
735959. Respirator. Eugene Folkmar, Charlottenberg, near Berlin, Germany.
736086. X-ray tube. Robert Friedlander, Chicago.
735968. Massaging implement. Julius J. Grobe, Chicago.
736250. Making hemoglobin preparations. Friedrich Hanssen, Altona-on-the-Elbe, Germany.
735876. Hot water bottle. Joseph Holland, Akron, Ohio.
736111. Inhaling apparatus. Theodor Kautz, Bad Reichenhall, Germany.
736328. Sterilizable surgical instrument case. Helen P. Wilson, Vanwert, Ohio.
734213. Hot water bag. Joshua Barnes, Smithtown Branch, N. Y.
734252. Lung testing apparatus. Paul von Boeckmann, New York City.
734159. Stethoscopic instrument. Robert C. M. Bowles, Boston.
734302. Siphon filler. Henry Carmichael, Malden, Mass.
734229. Fumigating and disinfecting device. George F. Hardinge, Vineland, N. J.
734323. Bottle closure. William Harrison, Redhouse, W. Va.
733977. Massage apparatus. Francis G. Lagerstrom and A. G. Anderson, Salina, Kas.
734270. Eye shade. Orlando B. Lester, Washington.
734238. Depurator. Augustus W. Ottignon, Seattle.
12133. Reissue. Massage machine. Charles Pfanschmidt and J. Siefert, Chicago.
734498. Dilating bougie. Friedrich R. Bachler, Oxnard, Cal.
734663. Ointment or pill slab. William Bower, Olney, Ill.
734849. Making sulphuric acid. Gustave Gin, Paris.
734586. Obstetrical instrument. Hiram Mendenhall, Audubon, Iowa.
734926. Artificial foot. William F. Mumberg, Chicago.
734952. Massage apparatus. John A. Reade, Jr., Chicago.
735043. Sanitary pocket cuspidor. John Tobin, Brooklyn.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending August 15:

A. A. Surgeon P. L. Cooke, detached from the *Chesapeake* and ordered home to wait orders.

Surgeon J. M. Edgar, detached from the *Wabash* and ordered to the Asiatic Station with a detachment of marines, leaving Washington August 24.

Surgeon G. B. Wilson, detached from the Naval Hospital, Chelsea, and ordered to the *Wabash*.

Asst.-Surgeon R. W. Bachmann, detached from the *Solace* and ordered to the Naval Station, Guam.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the fourteen days ended Aug. 6, 1903:

Assistant Surgeon-General W. J. Pettus, granted leave of absence for twenty days from August 10.

Surgeon H. W. Austin, granted leave of absence for one month from August 6.

Surgeon H. R. Carter, granted leave of absence for one month from August 4.

Surgeon J. B. Stoner, granted extension of leave of absence for one month from August 1.

Surgeon J. M. Gassaway, granted leave of absence for two months from August 10.

Surgeon Fairfax Irwin, granted leave of absence for two months from September 5.

Surgeon D. A. Carmichael, to proceed to Washington, D. C., and report to director of the Hygienic Laboratory for special instructions.

P. A. Surgeon B. W. Brown, granted leave of absence for fifteen days from August 12.

P. A. Surgeon J. M. Eager, detailed to represent the service at the International Congress of Hygiene and Demography at Brussels, Belgium, Sept. 3-8, 1903.

P. A. Surgeon H. W. Wickes, granted leave of absence for one day, August 15.

P. A. Surgeon L. L. Lumsden, relieved from temporary duty at San Juan, P. R., and directed to proceed to Vineyard Haven, Mass., and assume temporary command of service during absence of Surgeon D. A. Carmichael.

P. A. Surgeon J. A. Nydegger, relieved from duty at Sault Ste. Marie, Mich., and directed to proceed to the Immigration Depot, New York, N. Y., and report to Surgeon G. W. Stoner for assignment to duty.

P. A. Surgeon J. F. Anderson, to proceed to Marietta, Conewaga and Swiftwater, Pa., and Baltimore, Md., for special temporary duty.

Asst.-Surgeon C. E. Decker, placed on waiting orders from August 1.

Asst.-Surgeon W. K. Ward, granted leave of absence for ten days from August 25.

Asst.-Surgeon C. E. Decker, granted extension of leave of absence, on account of sickness, for fifteen days from July 15.

Asst.-Surgeon T. F. Richardson, to proceed to Tampico, Mexico, for special temporary duty.

Asst.-Surgeon C. E. D. Lord, to proceed to Seattle, Tacoma, Port Townsend and Sumas, Wash., Victoria and Vancouver, B. C., Portal, N. D., and Winnipeg, Manitoba, for special temporary duty.

Asst.-Surgeon C. W. Wille, to proceed to Baltimore, Md., and assume temporary command of the service during the absence, on leave, of Surgeon H. R. Carter.

Asst.-Surgeon L. P. H. Bahrenburg, on the arrival of A. A. Surgeon Norman Roberts at Chicago, to proceed to New Orleans and report to medical officer in command for temporary duty.

Asst.-Surgeon A. M. Stimson, granted leave of absence for seven days from July 28, 1903, under paragraph 191 of the Regulations. Granted extension of leave of absence for seven days from August 5.

Asst.-Surgeon W. K. Ward, granted leave of absence for two days from July 30, 1903, under paragraph 191 of the Regulations.

Asst.-Surgeon A. D. Foster, to proceed to St. Louis and assume temporary command of the service during the absence, on leave, of Surgeon J. M. Gassaway.

Asst.-Surgeon Norman Roberts, to report to medical officer in command at Chicago for duty and assignment to quarters.

Asst.-Surgeon G. L. Collins, to proceed to the Immigration Depot, New York, and report to Surgeon G. W. Stoner for duty.

Asst.-Surgeon H. G. Ebert, to proceed to Fort Stanton, N. M., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon W. M. Wightman, to report to medical officer in command at San Francisco quarantine for duty and assignment to quarters.

Asst.-Surgeon H. M. Manning, to proceed to Stapleton, N. Y., and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon F. C. Smith, to proceed to the Immigration Depot, New York, and report to Surgeon G. W. Stoner for duty.

A. A. Surgeon B. J. Brown, Jr., granted leave of absence for two weeks from August 4.

A. A. Surgeon J. M. Delgado, granted leave of absence for seven days from August 5, under provisions of paragraph 210 of the Regulations.

A. A. Surgeon F. Duffy, granted leave of absence for ten days from August 12.

A. A. Surgeon C. M. Frissell, granted leave of absence from August 6 to 18.

A. A. Surgeon R. S. Primrose, granted leave of absence for fifteen days on account of sickness.

A. A. Surgeon W. L. Savage, granted leave of absence for thirty days from August 6.

A. A. Surgeon P. N. Barnesby, granted leave of absence for one month from August 6.

A. A. Surgeon W. A. Klimmet, granted leave of absence for two days from July 25, 1903, under paragraph 210 of the Regulations.

Pharmacist F. A. Southard, on being relieved by Pharmacist C. R. McBride, to proceed to Washington, D. C., and report to the director of thee Hygienic Laboratory for duty.

Pharmacist M. H. Watters, granted leave of absence for twenty-two days from August 15.

Pharmacist C. R. McBride, to proceed to New York (Stapleton) and report to medical officer in command for duty and assignment to quarters.

Pharmacist Henry Gahn, detailed to represent the service at the fifty-third annual meeting of the Pharmaceutical Association, to be held at Mackinac Island, Mich., August 3. Reassigned to duty in the Purveying Depot, effective July 17.

Pharmacist A. M. Roehrig, detailed to represent the service at the fifty-third annual meeting of the Pharmaceutical Association, to be held at Mackinac Island, Mich., August 3.

Pharmacist W. L. Stearns, reassigned to duty at the Purveying Depot, effective July 17.

Pharmacist R. H. Gibson, granted leave of absence for seven days from July 29, 1903, under paragraph 210 of the Regulations.

Pharmacist L. W. Ryder, granted leave of absence for fifteen days from August 1.

Pharmacist M. H. Watters, relieved from duty in the Hygienic Laboratory and assigned to duty in the Bureau. To report to chairman of board of examiners at Washington, D. C., Aug. 10, 1903, for examination to determine his fitness for promotion to the grade of pharmacist of the second class.

Pharmacist L. P. Hall, granted leave of absence for thirty days from August 20.

BOARDS CONVENED.

Board convened to meet at Washington, D. C., July 27, 1903, for the consideration of the request of Asst.-Surgeon C. E. Decker to be placed on waiting orders on account of physical disability. Detail for the board: Assistant Surgeon-General A. H. Glennan, chairman; Assistant Surgeon-General L. L. Williams; Assistant Surgeon-General H. D. Geddings, recorder.

Board convened to meet at Washington, D. C., July 27, 1903, for the physical re-examination of an officer of the Revenue Cutter Service. Detail for the board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon-General H. D. Geddings, recorder.

Board convened to meet at Washington, D. C., August 10, 1903, for the examination of Pharmacist M. H. Watters to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the board: Assistant Surgeon-General L. L. Williams, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

APPOINTMENTS.

Norma Roberts, Pennsylvania; George L. Collins, Massachusetts; Harvey G. Ebert, Washington; William M. Wightman, California; Herbert M. Manning, District of Columbia, and Frederick C. Smith, Minnesota, commissioned as assistant surgeons (recess) in the Public Health and Marine-Hospital Service.

Charles R. McBride, Ohio, appointed pharmacist of the third class, Aug. 7, 1903.

PROMOTION.

G. W. Iltis, pharmacist of the third class, promoted to be pharmacist of the second class, effective April 24, 1903.

REINSTATEMENT.

William C. Phillips, reinstated as pharmacist of the third class.

SUSPENSION.

Pharmacist H. E. Davis, suspended from duty and pay for a period of thirty days from July 27, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Aug. 15, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, August 1-8, 4 cases.
California: Los Angeles, July 25-August 1, 1 case; San Francisco, July 26-August 2, 3 cases.
Massachusetts: Fall River, August 1-8, 1 case, 1 death.
Michigan: Detroit, August 1-8, 3 cases.
Missouri: St. Louis, August 1-8, 6 cases.
Nebraska: Omaha, August 1-8, 1 case.
New Hampshire: Manchester, August 1-8, 1 case.
New Jersey: Camden, August 1-8, 4 cases.
Ohio: Cincinnati, July 31-August 7, 2 cases; Dayton, August 1-8, 3 cases; Toledo, August 1-8, 1 case.
Pennsylvania: Allegheny, August 2-9, 5 cases, 1 death; Altoona, August 1-8, 1 case imported from Virginia, via Washington City; Carbondale, July 24-31, 2 cases; McKeesport, August 1-8, 4 cases.
Utah: Salt Lake City, August 1-8, 2 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, July 18-25, 3 cases.
Ecuador: Guayaquil, June 24-July 4, 1 sporadic case.
Colombia: Bocas del Toro, July 20-28, 1 case.
Great Britain: Bristol, July 18-25, 1 case; Leeds, July 18-25, 9 cases, 1 death; Liverpool, July 18-August 1, 12 cases, 2 deaths; London, July 11-25, 19 cases; Manchester, July 18-25, 7 cases; Nottingham, July 11-25, 10 cases.
India: Bombay, July 7-14, 14 cases; Calcutta, July 4-11, 1 case.
Mexico: City of Mexico, July 26-August 2, 7 cases, 4 deaths; Tampico, August 1-8, 2 deaths.
Netherlands: Amsterdam, July 25-August 1, 1 case, 1 death.
Russia: Moscow, July 11-18, 2 cases.

YELLOW FEVER.

Colombia: Panama, July 27-August 3, 3 cases, 1 death.
Costa Rica: Limon, July 23-30, 2 cases, 2 deaths.
Mexico: Tampico, July 24-August 8, 35 deaths; Vera Cruz, July 24-August 8, 91 cases, 29 deaths; Victoria, August 10, 1 case, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, June 13-20, 9 cases, 8 deaths; Provinces, June 13-20, 368 cases, 319 deaths.

CHOLERA—FOREIGN.

India: Bombay, July 7-14, 1 death; Calcutta, July 4-11, 35 deaths.
Straits Settlements: Singapore, June 13-20, 6 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, July 29, 1 death.

PLAGUE—FOREIGN.

Australia: Queensland, Bundaberg, June 1, 1 case.
China: Hongkong, June 17-26, 52 cases, 47 deaths.
Egypt: Alexandria, July 5, 1 death; Port Said, July 13, 7 cases; Tantah, July 9, 4 cases.
India: Bombay, July 7-14, 68 deaths; Calcutta, July 4-11, 15 deaths; Karachi, July 5-12, 2 cases, 2 deaths.
Mauritius: July 2-16, 11 cases, 10 deaths.

SKIASCOPY AS A METHOD OF PRECISION.*

EDWARD JACKSON, M.D.
DENVER, COLO.

It is difficult to realize how one may understand the theory of a method, and may employ it habitually in practice, and yet may attain results of insignificant value, as compared with what might easily be reached by a little more exactness. The difference between a loose method and a method of precision may be nothing in theory and trifling in detail, but enormous in practical usefulness. A scientific method becomes a method of precision, and attains practical value by comparatively slight modifications, but these may be made or adopted very slowly.

We can better understand how slowly by looking at the history of a diagnostic procedure that is now generally relied on. It is more than three hundred years since the invention of the thermometer. About two hundred years ago it was perfected in practically its present form by Fahrenheit. Yet physicians still in active practice remember the work of Andral and Wunderlich which made thermometry a method of precision in practical diagnosis, and led to its general adoption.

Take the clinical thermometer as we have it to-day, and the literature which now gives significance to its readings; but use it with neglect of a few precautions necessary to accuracy, and the observations made with it would be worthless. Drop precision from any modern method of examination and what a farce it would become. In no branch of modern science is minute exactness of greater importance than in the measurement of the refraction of the eye.

Skiascopy has been much written about and practiced of late years. It has given results that justify this. But by attention to certain details that would render it a method of precision, its practical value would be increased ten-fold. Skiascopy is a method of physical measurement. It is capable of exactly the same certainty as measurement by the rule or balance; and upon the same condition, exactness. Such statements as it "is not trustworthy when subjective methods are possible with intelligent people," or "it is sometimes misleading," indicate merely the carelessness with which it has been used. If your thermometer be falsely graduated, or your tape measure stretches freely, and you do not know enough about them to appreciate the dangers of such inaccuracies, you may be misled by them. If you measure by skiascopy the periphery of a dilated pupil, never used in vision, and do not know that its refraction is totally different from that of the visual zone at the center of the pupil, you may be misled by skiascopy. The shadow test is trustworthy enough. It is ignorance, haste, carelessness, inexactness that are untrustworthy.

It was inevitable that this method of examination should pass through a period of development. The ophthalmoscope, which came as near being a complete discovery as any we have had, has grown enormously in practical value since its introduction. For skiascopy this stage of development has not yet passed, but it has gone far enough for us to place the shadow-test among our methods of precision. The time for being content with a general comprehension of its theory, and teaching it in a rude, diagrammatic way has passed. Recognition of it as a practical test should be given henceforth only as it takes the form of a method of precision. If one has no tape measure he may estimate length by spanning with his hand or counting paces. If the conditions for accuracy are for the time impossible, one may practice approximate skiascopy. But it should be recognized that this is not all that skiascopy might be.

The first step toward rendering skiascopy a method of precision is the shortening of the distance between the patient and surgeon. We do not try to recognize the diplobacillus or the gonococcus with a magnifying power of two hundred diameters or less. Why should we try to practice skiascopy at the distance of one meter, where it is impossible to recognize appearances which must be recognized in order that the skiascopic determination of the refraction shall be accurate?

The shadow-test is practiced with a pupil of from 4 to 8 mm. in diameter. A letter inscribed in a circle of that size would be recognized at a distance of 2 to 4 meters in a good light. With the strongest illumination of the pupil the movements of light and shadow can be recognized readily at the same distances. But the strongest illumination is not available for accurate skiascopy. The conditions which give the most brilliant reflex from the pupil differ essentially from those under which the refraction can be exactly measured. As the point of reversal is approached the illumination of the pupil becomes feeble, and for a fair approach to exactness, say within 0.25 D., the light in the pupil becomes so feeble that the direction of its movement can not be recognized at one meter, even when the movement extends over the whole width of a pupil 6 or 8 mm. in diameter. Skiascopy at one meter can not be certain. The correctness of measurements made at that distance can not be relied on. They may be accurate by chance, but they are not accurate with certainty.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

Moreover, in the great majority of eyes, the movement of light and shadow has to be determined, not in the area of the whole pupil, but in an area much smaller, a circle of 3 to 5, instead of 6 to 8 mm. in diameter. Then in this smaller circle one has to watch the movement of a comparatively dim light area, while around it a larger and more brilliant area is also moving. The folly of getting so far away that it is difficult or impossible to recognize this important central movement, has greatly lessened the practical value of the shadow-test.

The reasons that this folly has continued so long, and has been so general, are not difficult to imagine. If you wish to make skiascopy a method of precision, you must be careful as to all its details. The source of light must approximate as closely as possible a mathematical point. The distance between surgeon and patient must be measured exactly. But if the surgeon goes far enough away from the patient's eye, it makes very little difference whether his source of light be large or small, and he need not measure the distance from the patient at all, but merely guess at it or make a fixed deduction.

If skiascopy is not to be a method of certainty and precision, but only a rough and approximate test, the loose, easy, careless way of practicing it will answer. But it ought to be generally understood that this loose method no more exhausts the possibilities of skiascopy than did the old methods of the alchemists exhaust the possibilities of the chemical examination of urine.

The time will surely come when our profession will appreciate the value of an objective method of exactly measuring refraction, and will hold in light esteem the scientific judgment of a generation that failed to appreciate that value. But until such a method of precision is appreciated, not even the most reasonable and obvious of its essential conditions is likely to be generally observed.

The need of measuring the distance between surgeon and patient has already been alluded to. When the distance is so great that a foot added to it will mean but 0.25 D. difference in the refractive power, such measurements are unnecessary. But when a single inch means more than 0.25 D. of refractive power, the need for exactness is obvious.

The size of the retinal light area obtained with a certain source of light is inversely proportioned to its distance. If the source of light be kept of the same size and brought nearer to the patient's eye, the delicacy of the test will be diminished rather than increased because of the enlarged retinal light area. A source of light I cm. in diameter, used at ten inches, will be as inaccurate as a source 4 cm. in diameter, at one meter. For working at one-quarter meter we must reduce the diameter to 2.5 mm. or less. The need to give the sight-hole a sharp edge and circular form is generally appreciated. It becomes even greater as skiascopy is rendered a method of precision.

The reduction in the size of the source of light renders necessary a reduction in the sight-hole, to prevent the reflected light point from being largely or completely swallowed up in it. The sight-hole should be not more than half the diameter of the source of light. Of course, with such a sight-hole its freedom from reflection, which should always be aimed at, is essential.

When skiascopy has been developed and modified in these respects, still other things assume practical importance. The room must be thoroughly darkened. The more delicate movements of the faintly illuminated area in the pupil can only be perceived when the surgeon's retina has become adapted to a faint light. Then, too, this faint illumination must not be overcome by reflexes from the trial lenses in front of the patient's pupil. The light must be so thoroughly cut off that no reflection of the surgeon's hand, or face, or other object can interfere with the watching of the pupillary movement.

To get the rays entering through the patient's pupil accurately focused on the retina, the source of light has to be brought as close as possible to the mirror, and this position brings it also comparatively close to the patient's face. When the distance between surgeon and patient is reduced to 12 inches or less, this renders worth while a double metal shade, which will prevent unpleasant heat from the flame.

To fix exactly the principal meridians of astigmatism, special arrangements are required. The correcting cylinder turned to its proper meridian often serves the purpose. But for higher degrees of astigmatism (more than 0.50 D.) the wire stretched in front of the pupil, as suggested by Finch, is more satisfactory.

So many of these points must be attended to if we would render skiascopy a method of precision, and so interdependent are they, each losing most of its value when not used in connection with the others, that it seems proper to recognize a special form of the shadow-test as exact skiascopy. This we can do while fully appreciating that in essential theory and general character it is identical with the shadow-test in general. It is distinct in the sense that perimetry is distinct from measuring the field of vision with the fingers or by other methods; or as the refraction of the ophthalmoscope is distinct from the original Helmholtz or Liebreich ophthalmoscopes.

We would indicate by the term exact skiascopy:

The working at a distance of one-quarter to one-half meter.

The accurate measurement of the distance.

The adaptation of the source of light and the sight-hole to this distance.

Care to bring the source of light close to the conjugate focus of the retina.

Means of fixing exactly the direction of the principal meridians.

Control testing, by departure both ways from the lens' strength, focal distance, or meridian fixed on.

And, in general, precision and exactness in every detail.

Such a method of examination is capable of sufficient accuracy for ordinary practical purposes. It will fix the error of refraction within one-quarter diopter, and in many eyes within one-eighth diopter, and the direction of astigmatism within 5 degrees when the astigmatism amounts to 0.75 D. or over, and within 15 degrees when it is only 0.25 D.

In recognizing the fact that skiascopy will not determine the refraction of all eyes with equal accuracy, it must be remembered that this is true of all methods of measuring refraction, and most true of those that give the most exact results, especially the subjective test with trial-lenses and test-letters.

It is not admitted that skiascopy is in this respect inferior to other methods. As a matter of fact, it can be relied on more completely than any other method now in use. Having made the skiascopic examination, one can judge far better of the amount of confidence to be placed in its results, than he can judge of the value of the

results obtained by the subjective methods or with the refraction ophthalmoscope. The illuminated pupil shows not only a certain error of refraction; it shows also whether the refraction is the same throughout its whole area, or throughout a definite visual zone. If this be not the case, so that some uncertainty attaches to the measurements made in any particular case, exact skiascopy reveals this fact also, and thus guards against undue confidence in its own findings.

DISCUSSION.

Dr. O. A. Griffin, Ann Arbor, Mich.—Subjective tests are certainly unreliable in a great many instances, and to secure satisfactory results other methods must be employed. When we remember that 90 per cent. of ametropes are astigmatic, one-quarter diopter or more; that a sphere will improve vision in astigmatic conditions up to about one-half of the measure of the error, and that normality of sight does not exclude the existence of small refractive errors, especially astigmatic, we must depend on a more reliable method than that furnished by the uncertainty of a patient's judgment.

It is important, as Dr. Jackson has indicated, that we follow the method in all its details in order to secure accurate results. I often find refractionists disappointed with the method simply because they do not understand how to use it. Instead of watching the movements of the shadow in a small central area, they observe the cornea as a whole. In some cases where there is an unusual amount of spherical aberration the scissors-like movements of the shadow will prove annoying, when the peripheral movements should be ignored, as the rays do not pass through this area when the pupil is normally contracted.

I am somewhat surprised that Dr. Jackson discredits the accuracy of results obtained at one meter. I make all my estimations at that distance, and in the majority of instances can easily differentiate between a quarter and eighth diopter of error. There are cases where we meet with opacities of the media or sufficient irregular astigmatism to interfere with the test; but fortunately these conditions are rare, and do not interfere enough to condemn the method.

It is, I think, in the correction of strabismic ametropias that skiascopy proves of exceptional value. If strabismus is produced by ametropic conditions, then it is imperative that these errors should be corrected early. If one depends solely on subjective tests, as is too often the case, the ametropia can not be properly estimated until the child becomes old enough to read, by which time an irreparable amblyopia has often occurred, whereas with the skiascopic test the condition can be corrected as soon as it shows itself. I have often employed the method in refracting children of tender years, and think it exceedingly fortunate that we have such a reliable objective test at our command. The statistics show, I believe, that fully one-third of strabismic conditions can be remedied by an early correction of the ametropic condition alone. If this be true, the importance of objective tests can not be overestimated.

Dr. Harold Gifford, Omaha—I do not understand why the author speaks of the visual "zone." Why not call it visual area instead of visual zone. This area is not a belt around a sphere, as that name would indicate, and the area is often not even circular.

Dr. Wm. H. Wilder, Chicago—Although I appreciate the value of the method of skiascopy advocated, and while there is no question of the method being the most accurate means of testing the refraction, it seems to me in most cases an unnecessary refinement because of being more laborious. I am sure that anyone with care and skill at a distance of one meter can get as close as a quarter diopter to the refraction of almost every case. I feel satisfied whenever I am within a quarter diopter of the actual truth. That is close enough for all practical purposes, for with that you can prescribe with safety in children unable to read. Of course, the subjective test at the reading chart is the final one. I make use of the concave mirror, with the light behind the patient's head. The error is only slight at a meter as compared with that which may occur at a distance of 20 to 30 centimeters.

Dr. C. W. Hawley, Chicago—I think perhaps some will misunderstand Dr. Jackson's paper. I do not believe he means that for practical work the examination must be done with the accuracy of which he speaks, but that he is pointing out the manner in which it must be done in order to correspond scientifically with other methods of accuracy. I know it can be depended on. A distance of one meter is what most of us use, but we find that sometimes we must get a little nearer or a little further away; that is a matter learned only by experience. As to the correction of one's own error of refraction, that is a matter of special importance to older men. A man who is a presbyope must correct that condition up to the distance at which he works. That I have learned by my own practical experience. While in London a certain physician gave it up in disgust, and I have never known until the last few years why he did so; it was because he was a presbyope and had not corrected that condition. When I became a presbyope I began to get very inaccurate, and could find no reason for it, when it dawned on me one day to correct my presbyopia, and it was a revelation to me. At about the same time I taught one of my friends to use the method. He was very much like my friend in London and was about to throw it aside. I asked him if he had tried using his glass correcting his presbyopic condition, and he said he had not. He had his lens placed at the back of his mirror and now does retinoscopy with pleasure and accuracy. Place on the back of your mirror a little frame for the lens, or have a permanent lens correcting the presbyopia at the distance at which you ordinarily do retinoscopy attached to the mirror. Those who have a large amount of astigmatism and hypermetropia must, of course, do the same.

Dr. Edward Jackson, Denver—With reference to the point raised by Dr. Hawley as to the correction of presbyopia, of course the correction of one's own error is only important as giving him distinct vision. When we attempt to use the method with accuracy we work up to the limit of visual acuteness and must have perfect vision to get the best results. As for myself, I have trouble with the ocular muscles more than with the accommodation. I find the illuminated pupil getting off on the brow or cheek as seen with the other eye. I have sometimes thought of adapting a prism behind my mirror as Dr. Hawley has adapted the lens. A small amount of presbyopia may give trouble.

As to Dr. Gifford's remark about the visual zone, I think zone may be used to designate that kind of an area. It is a circle within a circle. It is a circular area around the axis which I refer to as the normal visual zone.

As to the matter of working at a distance of one meter: You can not be sure of the amount of astigmatism within a quarter diopter at that distance. You may determine it in many eyes, but not in all. If you want to be accurate in every case it will be worth while to use the method which can be most accurate and most easy. At a half meter or less you can recognize everything more readily. The observed pupil is three or four times the area that you get at one meter. Perhaps the most important thing is the fixing of the axis of astigmatism, especially of low degrees. For that we have no other method approximating in exactness this method of skiascopy.

Local Treatment of Rheumatism.—Testimony is accumulating in our European exchanges that the local application of the methoxymethylester of salicylic acid has a remarkably soothing effect on rheumatic pains. In cases of rheumatism due to getting chilled the pains are banished by rubbing the part with a teaspoonful or tablespoonful of the drug, either pure or in a 50 per cent. oily solution. In obstinate cases of rheumatism it effectively supplements internal salicylic medication and relieves even chronic, hopelessly rebellious cases. It has not proved effective in neuralgia, but has been very useful in the declining stage of acute articular rheumatism, etc. It is put on the market under the name of Mesotan.

RETINAL DISEASE LIMITED TO THE REGION OF THE FOVEA.*

HENRY GRADLE, M.D.
CHICAGO.

In the course of years there have come under my observation five instances of disease of the retina sharply limited to the fovea and its immediate neighborhood. As I am not aware of any similar observation on record the cases seem to me to be worth reporting on account of their diagnostic interest. The only analogous disease resembling this affection is the central retinitis with scotoma caused by sunlight; for instance, while watching an eclipse. Since the cases observed by me were alike merely in localization, but different in clinical course and presumably in etiology, I see no object in generalizing, but shall only comment on the individual observations.

ACUTE CENTRAL RETINITIS WITH RECOVERY.

CASE 1.—Mr. N., a man of 45 years, in good health except for some dyspeptic symptoms, had complained lately of beginning presbyopia. He awoke one morning and saw a shadow in front of the left eye with slightly blurred sight. Two days later I found the sight in left eye 20/50, in right eye normal with a weak cylinder. He drew the brown shadow in the form of a horizontal ellipse with sharp outline extending about 3 deg. to the temporal and 6 deg. to the nasal side of the point of fixation. Within the scotoma all colors appeared faded. The fundus was not absolutely normal in both eyes. The papillæ were more injected than normally in both eyes and their edges not sharply defined. The central area of both retinæ showed a number of barely visible minute white but not glistening specks irregularly scattered. In addition, there was seen in the left eye and not in the right, a distinct though faint cloudiness of the region around and especially above the fovea. Media normal. Pilocarpin was ordered once a day, and a mild purge of calomel every second day.

Within the next ten days the shadow grew fainter, although it expanded a trifle at first. His sight rose to 20/30. The retinal cloudiness cleared visibly. About one week later (2½ weeks after the onset) the eye seemed to him normal. Three months later the retina of the left was as normal as that of the right eye. Both still showed the few white specks, but the optic discs were practically normal. His sight, corrected by cyl. +0.75, was 20/20 minus. No relapse after several years.

The lesion in this case was evidently an exudate in the anterior layers of the retina. For a shadow seen subjectively, or in other words, a positive scotoma, can only be caused by an opacity anterior to the sensitive layer of the retina. The retinal infiltration as seen by the ophthalmoscope appeared more diffuse than the sharply-defined scotoma. It seems logical to call the lesion a central circumscribed retinitis. Nothing could be ascertained as to its cause or the reason of its localization. It is impossible to say to what extent the recovery depended on the treatment. My general experience in various forms of neuritis and retinitis leads me to credit the calomel largely for the success, while I have lost all faith in the efficacy of pilocarpin.

ACUTE CENTRAL RETINITIS WITH RECOVERY, BUT SUBSEQUENT RELAPSE.

CASE 2.—Mr. S., active business manager, in good health, 55 years old, noticed one day a small brown shadow before the right eye with a heavy feeling and slight blurring. Two weeks later I found the left eye normal subjectively and objectively. The sight of the right eye was barely 20/40, while it had formerly been 20/20 minus with cyl. +05D. He draws on paper the circular outline of a shadow of about 4 deg. radius. The center of the retina of the right eye showed two oval spots, one above the other (like a figure 8), each about one-sixth of a papillary diameter, yellowish, sharply defined, but very faint and surrounded by a zone slightly darker than the rest of the fundus. Fovea as such not visible.

After a dose of calomel and the use of dark glasses vision rose to 20/30 in two days. He was unable to tolerate iodin, but took a few more doses of calomel. Within two weeks the shadow was gone, vision was normal and the morbid figure in the retina could scarcely be recognized.

Eighteen months later the same shadow reappeared in the right eye and vision again dropped to 20/30. The ophthalmoscope showed a yellowish discolored spot again involving the center of the retina, more irregular in outline than before, about one-fourth papillary diameter with more pigment granules in it than formerly. Again the shadow and blurring disappeared almost completely in two to three weeks under the use of calomel every second or third day, but the fundus lesion did not change. He told me subsequently that his vision was normal, but that a very faint shadow was still noticeable. I got no opportunity, however, to examine him with the mirror.

The comments made on Case 1 apply equally to this patient. The lesion, however, appeared different ophthalmoscopically, probably on account of some changes in the retinal pigment epithelium. The following case resembles Case 1 more closely, but unlike the other two, did not end in recovery:

CASE 3.—Mr. B., 40 years of age, healthy and with negative history, claims to have noticed a shadow with blurring about six months ago. He was treated by another oculist without improvement. The affected eye (the other being normal) has V.=20/50. He describes a gray shadow nearly crescentic and just below the point of fixation. It did not seem to be quite 5 deg. wide as indicated on the perimeter. The retina showed a fairly circumscribed grayish cloudiness, approximately semicircular, upward from the visible fovea. I did not see the patient again.

In all these instances the lesion was evidently of inflammatory origin and involved only one eye. The next case, however, showed symmetric lesions in both eyes. Neither the nature nor the time of occurrence of the disease could be learned, since only its permanent residues were seen.

CASE 4.—Mrs. S., now 37 years old, has always had poor sight, especially in the evening. Either eye has but 20/200 vision. According to all objective as well as subjective tests cyl. —2.5D. axis 110 deg. with sph. +0.75D. corrects the right eye perfectly and C.—1.75D. axis 90 deg. with sph. +0.75D. the left, but with this correction she scarcely reaches 20/100. The only anomaly shown by the ophthalmoscope is a very faint but unmistakable central lesion. The fovea as such is not recognizable in either eye, but on central fixation the foveal region, about ¼ papillary diameter, is seen a brighter red than the rest of the fundus, perhaps more so by reason of contrast, as this light red area is surrounded by a narrow zone of abnormally dense pigmentation.

The poor sight of this patient could not be accounted for by any optic reason, but is evidently explained by damage done in the center of the retina by some former possibly pre-natal disturbance. There was neither a positive nor a negative scotoma demonstrable, but simply imperfect function of the foveal region with integrity of color sense and of peripheral acuity of sight.

The last observation pertains to an insidious degenerative disease, also limited to the exact center of the retina.

CASE 5.—Mr. S., 42 years old, and in perfect health, was seen in October, 1894, on account of slight asthenopia and imperfect sight. The findings were: R. E., V.=20/70, with —0.75D. and cyl. —0.5D. axis 100 V.=20/30; L. E., V.=20/80, with —1.5D. and cyl. —1.D. axis 60 V.=20/20 minus, which glasses were given. Four years later slight failure of the

right eye caused him to return, when the corrected sight was found to be only 20/40. In 1899 it was not quite 20/50, without any change, however, except presbyopia in the left eye. At all these occasions a painstaking ophthalmoscopic examination, however, without dilatation of the pupil, revealed no anomaly. In November, 1901, after an interval of seven years, the sight of the right eye with full (unchanged) correction had sunken to 20/70. On dilating the pupil the only lesions to be seen were slight opacity in the extreme periphery of the lens and two spots each under ⅛ papillary diameter, one occupying the site of fovea, the other almost adjoining it. The spots were poorly defined, faint yellow in color, with scarcely noticeable increase of retinal pigmentation at the periphery.

There was in this case at no time any sudden disturbance of sight. The lesion was evidently of degenerative character, and of slowly progressive nature.

DISCUSSION.

DR. W. L. DAYTON, Lincoln, Neb.—The first two or three cases mentioned by the essayist simulate the changes at the macula that may occur with senility. The age of his patients, however, would not naturally warrant us in assuming this, yet I do not remember that he spoke of the refraction. It is possible even at that age that a very hyperopic eye might have some influence on this condition inasmuch as the changes in the fovea from senility undoubtedly occur in the nerve and pigment epithelium of the retina, and it appears to me possible for such changes to occur in the cases stated. I had a case somewhat similar to this third one under observation several years ago; a case of pernicious anemia, where the spot appeared to me as if it had been a hemorrhage of long standing—not black, but more of a reddish brown. The patient succumbed to the pernicious anemia. In retinal disease limited to the macula lutea there are a number of conditions that should be carefully studied. There are cases where foreign bodies have entered the vitreous and where some weeks afterwards there appear changes in the macula. This is important, too, because we may have to deal with the condition from a medico-legal standpoint, as bearing on accident insurance, etc. The changes may not appear until some weeks after injury, or extraction of a foreign body. We may find no evidence of foveal disturbance, and then after the eye has assumed its normal condition find changes about the fovea. We may think that we have to deal with a malingerer, and then a month or so later these macular changes be very evident. I have in mind a case where such changes about the fovea occurred, yellowish-white in appearance, three months after the injury. Then, as Dr. Gradle has said, there are changes in the macula in retinitis due to the effect of electric light, and there we get a similar condition. There is another condition that I would mention in this connection, and that is where there is but little disturbance of vision and where the ophthalmologic appearance is that of small white dots. This condition may not reduce vision to more than 20/25, and yet present this peculiar appearance. I have never been satisfied as to what the condition is.

DR. LEARTUS CONNOR, Detroit—I have observed a somewhat different case, in a physician 40 years of age. The history showed at a previous examination a healthy eye, until within two weeks of the time I saw him, when suddenly in his left eye central vision disappeared; peripheral vision was normal. A peculiarity he described was this: that this spot which he saw was alive, and he described and drew on paper the various movements observed subjectively; their outline was oval in shape, progressing from the center toward the border in all directions. The drawing I made from the ophthalmic picture corresponded with that made by the patient. Two months later his central vision had become 20/200 and was apparently improving. Evidently it had involved the entire structure of the retina and the cellular elements were in a state of activity during that period. Whether treatment had any effect or not I do not know. He had been a perfectly healthy man with no constitutional taint, but he had overworked while neurasthenic.

DR. C. W. HAWLEY, Chicago—I was much interested in the paper because it calls to mind three cases I had thought of reporting. The conditions about the macula are not exactly like those described by Dr. Gradle, except in one case. The three cases occurred in ladies and came under my observation some two or three months apart. The conditions about the macula were very much like those which occur in albuminuric retinitis less the hemorrhages. I treated the first case for some time and without much improvement. It finally passed into the hands of an irregular practitioner, was treated for constipation and the patient returned home cured, the macula having returned to its normal condition. The next case was similar and I turned it over to a general practitioner, with the same result. He treated the intestinal tract and the condition cleared up. The third case was very much the same, and all three were treated as to the intestinal tract. No investigations were made as to what the nature of the poison was, but I am sure the condition resulted from the intestinal poisoning.

I understand that Moses Gunn has described some cases very similar to these. I am sure Dr. Gradle's success is due to the doses of calomel he gave.

NEUROGLIA TISSUE AND EPENDYMAL EPITHELIUM IN TERATOID TUMORS.*

HENRY A. CHRISTIAN, A.M., M.D.

Instructor in Pathology, Harvard University; Second Assistant Visiting Pathologist, the Boston City Hospital, and Assistant Pathologist, the Children's Hospital.

BOSTON.

(From the Sears Pathological Laboratory of Harvard University, and the Pathological Laboratory of the Boston City Hospital.)

In pathology the advances by which our knowledge of any subject is obtained often take the form of a wave. An epidemic occasions renewed interest and furnishes abundant fresh material; a new technical procedure stimulates investigation and invites the reëxamination of accumulated material: the result is a series of contributions revealing new facts concerning the subject. Such a period of activity was inaugurated in the study of neuroglia tissue by the publication in 1895 of the staining methods of Weigert[1] and of Mallory.[2] Since then has come most of our knowledge of this tissue. Many investigators have been engaged on its problems, and other staining methods have been introduced, but none of these differential methods appears to have been applied to any extent in the examination of similar elements in teratoid tumors. In a teratoma of the ovary, some features of which have already been published,[3] a large amount of neuroglia tissue was found. This finding occasioned the investigation of other tumors of this class with particular reference to neuroglia elements. As in these tumors structures related to neuroglia occur and by the application of various neuroglia staining methods other elements than neuroglia fibers are brought out, it has seemed well to consider all of these in this study. Hence neuroglia fibers, neuroglia cells, ependyma, dots and fibers which stain by the neuroglia staining methods and retina-like structures will here be described and their significance discussed.

Teratoid tumors have from earliest times received much attention. A great variety of forms has been de-

---

scribed and all kinds of tissue, including the elements of the central nervous system, have been found in them. Their rate of growth and the symptoms due to their presence in various regions have been investigated. The contributions made to the various aspects of the subject have been reviewed repeatedly and it is not necessary to do so again at this time when it is our intention to consider mainly the histology of the neuroglia and of the ependymal epithelium in some of these tumors.

There were available for this study twenty teratoid tumors preserved in a way suitable for the application of neuroglia staining methods. Of these, 18 were from the ovary, one from the lung, and one from the anterior mediastinum. The tumors vary much in size and shape. Some consist of a single cyst with a solid ingrowth; some are solid cystic structures; others a combination of the two. All contain islands of bone and cartilage, some teeth. In six neuroglia was found. Of these, tumors 1, 2, 4, 5 and 6 arose in the ovary, tumor 3 in the lung. However, the possible presence of neuroglia in the others can not be denied, as it is manifestly impossible to exclude small areas of neuroglia except by serial examination of the tumor and this for such large tumors would be excessively laborious. For this reason and owing to the comparatively small number examined, these observations have no statistical value as to the frequency of the presence of neuroglia elements in teratoid tumors. They do show, however, that this tissue is of quite frequent occurrence in tumors not specially selected for complexity of structure.

Material from all of these tumors was fixed and preserved in 10 per cent. of formaldehyd. From some material was fixed in Zenker's fluid and preserved in 80 per cent. alcohol. Material fixed in formaldehyd was stained by Mallory's phosphotungstic acid hematoxylin method,[4] Mallory's modified fibrin method,[5] and Huber's modification of Benda's method of staining neuroglia.[6] That fixed in Zenker's fluid was stained by Mallory's anilin blue connective tissue stain[4] and the acid fuchsin potassium permanganate method very recently introduced by Mallory.[7] A number of variations and modifications of these methods were also employed and gave some interesting pictures. Besides these, alum hematein and eosin, or eosin and Unna's alkaline methylene blue were used. As many of these methods as possible were utilized in the study of each tumor.*

Neuroglia tissue is most abundant in tumor 1. The tumor consists of a single large cyst, with epidermal lining and an equal amount of tissue containing innumerable cysts, varying in size from very minute ones to those measuring several cm. in diameter. Between the cysts the neuroglia is scattered in masses of varying size and shape. None of these exceeds 1 cm. in greatest diameter. Most are very much smaller. Many of the areas are sharply circumscribed from the surrounding connective tissue. Into others strands of connective tissue penetrate or, on the other hand, a band of neuroglia makes its way for some distance from an otherwise sharply contoured mass into the surrounding connective tissue. Less often there is so intimate an intermingling along the border of the two tissues that the limits of the neuroglia can with the greatest difficulty

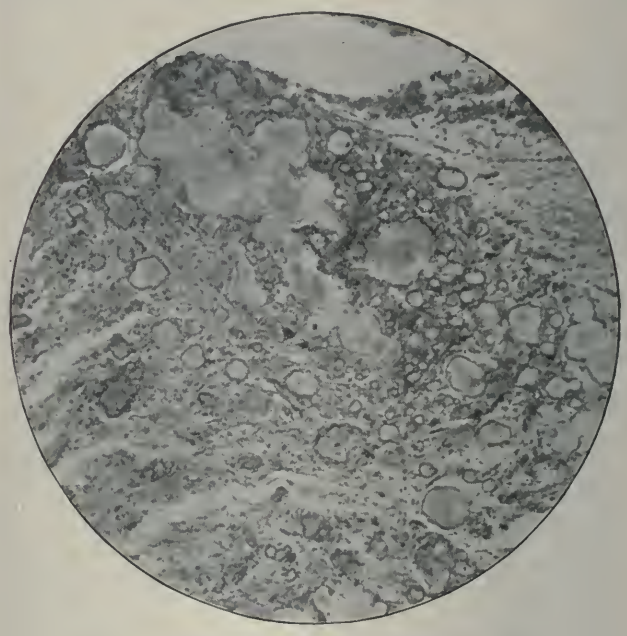

Fig. 1.—Corpora amylacea in neuroglia tissue.

be made out. In some sections single fibers or groups of several parallel fibers which resemble neuroglia fibers are found in the midst of connective tissue. These fibers are either fine or coarse, and have the same general direction as the surrounding connective tissue fibers. They may bear no relation of continuity to any mass of neuroglia tissue, and may be unaccompanied by any cell dif-

fering in appearance from the ordinary type of connective tissue cell.

The relation of the neuroglia to the cysts varies. Many neuroglia masses are entirely separated by connective tissue from the cysts. Others abut on or project into cysts. Some cysts are completely surrounded

* Weigert's method of staining neuroglia was tried, but satisfactory results could not be obtained. This may have been due to the fact that the tumors were not hardened soon enough after removal from the body or that the reagents used by me differed in some way from those originally employed by Weigert. On this account deductions made by me in regard to neuroglia staining methods are not to be taken as applying to the Weigert method.

by neuroglia. There may be a large cyst with a comparatively thin layer of neuroglia about it or cysts of varying size may lie in the midst of large masses of neuroglia. Where the neuroglia is adjacent to a cyst it may be naked or covered by epithelium. The epithelium covering the neuroglia is of two general types. The one is flat cuboidal and lies immediately on neuroglia fibers, though none penetrates between them; the

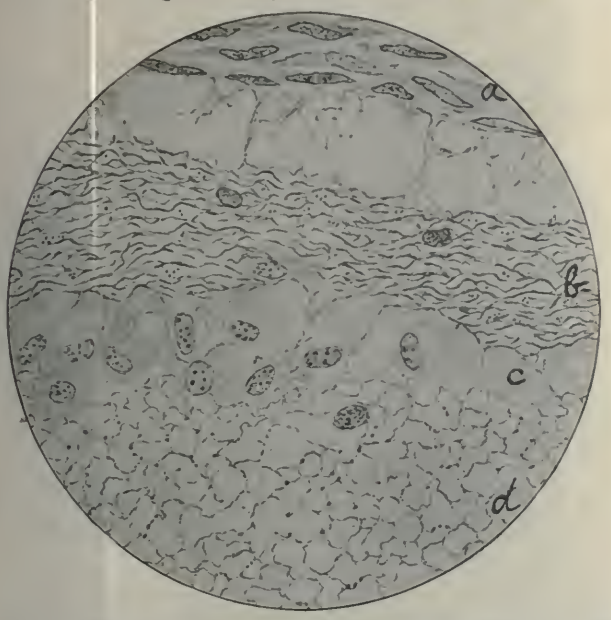

Fig. 3.—Neuroglia tissue. (*a*) Band of surrounding connective tissue. (*b*) Band of quite fine neuroglia fibers in general, running longitudinally and enclosing few cells. In this figure the dots represent cross sections of fibers.

other is of high cylindrical type, and between these neuroglia fibers often penetrate to a varying distance. Between these two types of cells are intermediate forms.

Tumor 1 shows greater complexity of neuroglia structure than the others. In tumor 2, with the same division into a large cyst and a solid portion, as in tumor 1, much less neuroglia is present. The solid portion of this tumor consists largely of small irregular cavities

Fig. 4.—Coarse neuroglia fibers ending in an expanded foot adjacent to a hyaline band of connective tissue. From base of so-called rosette.

and spaces, into which project papillary processes covered by high cylindrical epithelium containing goblet-like cells. In this respect it resembles a papillary adenocystoma of the type which is very common in the ovary. Besides this structure, in a few places are small cysts whose walls are lined by neuroglia. Tumor 3 shows numerous cysts, but the neuroglia tissue bears no close relation to these. It is sparingly present as small, irregular masses lying in connective tissue and sometimes abutting on a cyst.

In tumor 4 the neuroglia is present in relatively large masses. In one of these masses there is a central elongated cavity, which is not lined by epithelium. From this larger mass, bands of neuroglia extend into the surrounding tissue. In many places there is a very intimate intermingling of neuroglia and connective tissue fibers. In other places the two tissues are sharply demarcated. Tumors 4 and 5 each consist of a large

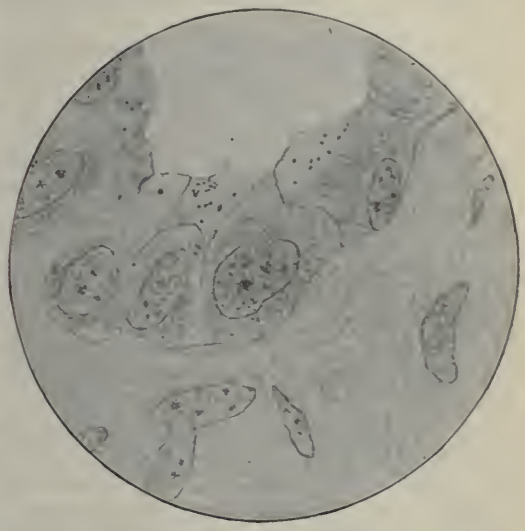

Fig. 5.—Part of a cyst lined by irregular cuboidal cells. In inner border of these are groups of "dots." In vicinity of cyst there is no neuroglia tissue. Section cuts cyst obliquely.

cyst, whose wall is not very thick. In this wall lie small, rounded masses and elongated bands of neuroglia. In one of the tumors numerous corpora amylacea of irregular size and shape are present in the neuroglia tissue (Fig. 1). In tumor 6 a single mass of neuroglia measuring 3 to 4 mm. in diameter is seen.

In the smaller neuroglia masses of all these tumors blood vessels are generally not present. In the larger masses they are found in moderate number and surrounded by a slight amount of connective tissue.

The appearance of the neuroglia in different areas is

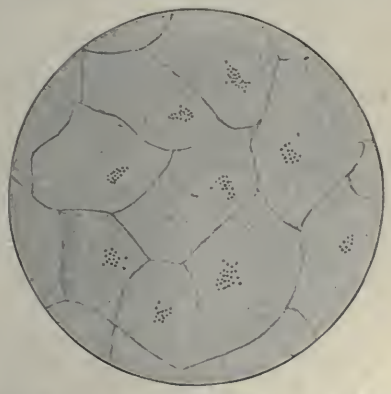

Fig. 6.—Groups of "dots" situated in the central end of cells lining a space. Section cut so as to give a view looking down on the top of the cells. Pale halo about some of the groups.

very various. The fibers differ in size and direction, the cells in form and frequency, and these differences are combined in an almost endless variety of ways. On the one hand we have masses of cells with but few fibers, on the other hand masses of fibers with infrequent cells. In neither extreme is the picture similar to that found normally anywhere in the central nervous system,

though both resemble types of gliomata. The most frequent arrangement is a coarse irregular meshwork of fibers, some fine, some coarse, crossing each other in all directions (Fig. 2). Scattered among these fibers cells are rather infrequent.

Instead of this arrangement, in many places, especially at the periphery of neuroglia masses, there is a more regular compressed meshwork of fibers having, in general, a parallel course (Fig. 3, b). Here nuclei are less frequent. Where these fibers are fine, the structure resembles that of the normal subpial and subependymal neuroglia.

A further modification in this direction results in bands of fibers, almost all of which run in the same direction and have practically a parallel course. In one or two instances these fibers are quite coarse and are interspersed with cuboidal cells roughly arranged in columns. This bears a slight resemblance to the arrangement of cells and fibers sometimes seen in tendons.

In places, instead of the interlacing fibers at first described, we have a finer meshwork of more delicate fibers and rather indefinite granular material, with nuclei widely scattered and generally having but little cytoplasm (Fig. 3, d). This arrangement of neuroglia fibers is similar to that found in many parts of the cerebral cortex.

The individual neuroglia fibers do not vary in diameter in different parts of their course and do not branch. Different fibers vary greatly in size. Some are very fine, others coarse, and some appear as narrow bands. In many areas the fibers are of approximately the same size (Fig. 3). In some the fine and coarse are mingled together (Fig. 2). For most fibers no definite method of ending is apparent; they apparently end abruptly or pass from the level of the section. Some, like those in the so-called rosettes, to be described later, end by an expanded foot applied to connective tissue (Fig. 4).

The cells, like the fibers, present a variety of appearances. Many have rather small, deeply staining, round nuclei, about which little or no cytoplasm can be made out (Fig. 3, b). Some, on the other hand, have abundant cytoplasm, though when the cytoplasm is abundant the nucleus is apt to be larger, oval or slightly irregular, and vesicular (Fig. 3, c). The larger nuclei contain a distinct rounded chromatin mass, besides scattered fine granules. Some nuclei are elongated or even spindle-shaped; where they have a narrow cytoplasmic zone around them they resemble the cells of dense connective tissue. A few of the larger cells possess two or three nuclei. Sometimes the smaller cells are closely packed in a rich network of fibers. At other times the large cuboidal or irregular cells lie close together, separated only by an occasional fiber (Fig. 3, c). In some places the picture is one of closely packed polygonal or elongated epithelial-like cells, with very few intervening fibers.

A number of the cells possess protoplasmic processes, but these are not very prominent. The fibers may be widely separated from the cytoplasm of a cell, and their closest relation appears to be one of contact, rather than of continuity. The cells have no cell membrane, and, whether round, oval, cuboidal, or irregular, their cytoplasm is rarely sharply demarcated, but gradually fades out at the periphery.

What is of particular interest is the presence in very many of the cells in the areas of neuroglia tissue of small dots, staining in the same manner as the neuroglia fibers. Often there is but one (Fig. 2). Sometimes there are two lying close together. Very frequently there are five to fifteen scattered in the cell or grouped together. They may have any position in the cell; sometimes they lie close to the nucleus, sometimes remote. Many times they are surrounded by a halo staining more palely than the general cytoplasm. Very rarely short rods, instead of dots, occur. These same

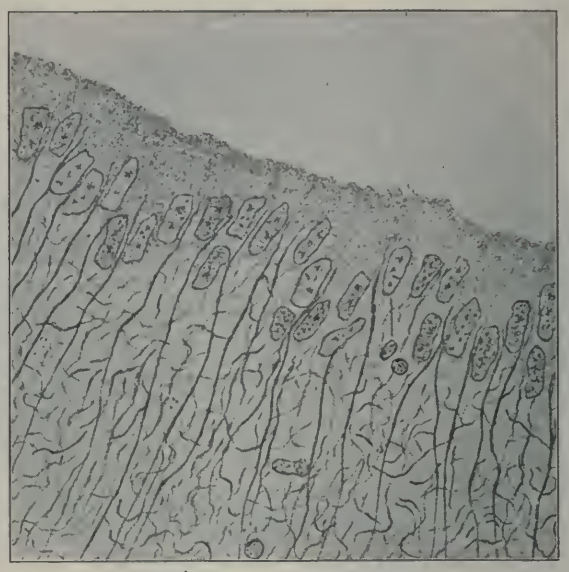

Fig. 7.—Ependymal epithelium lining a large space. Neuroglia tissue, with many rather coarse fibers perpendicular to ependymal layer and extending a short distance between the ependymal cells. From a preparation not stained by a method suitable for the demonstration of ependymal dots.

dots occur also in the epithelium of the cysts of the first tumor. Here they occur in the inner border or between the nucleus and inner border of the cells (Fig. 5). They can be best seen when the section cuts the cyst so that a view of the top of the cell is obtained (Fig. 6). The cysts which these cells line vary in size. They may be

Fig. 8.—A simple rosette.

minute, representing a small space or lumen in a group of cells, or they may be large. The cysts may have neuroglia in close proximity, or none be adjacent. In some cysts neuroglia fibers penetrate between the lining cells (Fig. 7). Of these cells some are low and cuboidal, and others high and cylindrical. Not infrequently in cili-

ated cells rows of these dots are situated at the base of the cilia. In others they are not present.

In tumor 1 are peculiar structures which deserve attention from their vague resemblance to retina and from their containing fibers which stain like neuroglia fibers. These partially fill some of the cysts. In their simpler form they consist of a rounded mass with a pedicle but little smaller than the mass (Fig. 8). The outer portion of this mass is made up of closely packed round or oval nuclei, sometimes deeply staining, sometimes vesicular with one to three rounded chromatin masses. The cytoplasmic bands of these cells are ill-defined, and be-

Fig. 9.—A more complicated rosette.

tween some of them fibers staining like neuroglia fibers can be traced. As the central and basal portions are approached there are fewer nuclei and more fibers. At the base there are almost no nuclei and many coarse fibers (Fig. 4). Most of these coarse fibers are parallel in direction and end against connective tissue by a fairly definite expanded foot. The connective tissue in this portion is frequently in the form of a hyaline band (Fig. 4), sometimes gently undulating, sometimes quite convoluted. Instead of this band there sometimes is a mass of indefinitely fibrillar or ill-defined hyaline connective tissue. In the region of the base there is always a layer of high cylindrical epithelium which passes by gradual transition into the epithelium lining the cyst. The ingrowth and fusion of several such masses produce more complicated structures (Fig. 9). The cysts in which they occur are almost always partially or completely lined by epithelial cells, which are filled with fairly coarse granules of brown pigment. This pigment resembles that found in the retina. The structures themselves resemble in many places the rosettes of gliomata retinæ, and, for need of a better word, may be called rosettes. They have similar small, round nuclei. The coarse neuroglia fibers ending in apposition to a connective tissue band suggest the fibers of Müller. Their occurrence in cysts lined with pigmented epithelium adds further to the analogy.

The mode of development of the structures described above can apparently be traced. At first there is a proliferation of the epithelium at one point in a cyst, resulting in a thickened layer of cylindrical cells, between which fibers staining like neuroglia appear (Fig. 10). The fibers and cells increase in number, and at the same time the connective tissue proliferates and pushes the mass into the cyst cavity (Figs. 11 and 12). The fibers grow mainly toward the base, while the cellular portion remains toward the center. In some cysts several such ingrowths are found (Fig. 13), and it is probable that in this way the more complicated masses are formed. Many variations in complexity are seen, and forms representing different stages of development appear in the various sections.

Discussion.—Nowhere in the central nervous system do we have such an intimate intermingling of neuroglia and connective tissue as in these teratoid tumors. In the brain and cord the separation between pia and cortex is usually sharp. Gliomata, as a rule, are in juxtaposition to surrounding white or gray matter or to pia, and so do not lie in very intimate contact with mesoblastic tissues. The nearest approach to these conditions is where vascular radicles, accompanied by a small amount of connective tissue, penetrate nerve tissue from the pia, and where the connective tissue of the choroid plexus abuts on neuroglia. In case of the teratoid tumors this mingling of the two tissues often occurs at points where no vascular radicles penetrate, but seems due rather to a coincident growth of adjacent foci of two tissues of different germ layer origin, with an overlapping, due to irregularity in rate of development. Such an explanation seems more plausible than that we have the one tissue invading preformed tissue of the other kind in the way a malignant tumor invades adjacent structures.

Moreover, there are present fibers in connective tissue remote from definite neuroglia masses. These stain in a manner identical with the neuroglia fibers of the larger masses, and in size, absence of branching, and undulating course present no differences from many fibers seen in them and in gliosis and gliomata. Their isolated presence in connective tissue seems difficult of explanation. At first it was assumed from their staining properties that they were to be considered of undoubted neuroglia origin. It was thought that their presence in connective tissue might be explained by their arising as an offshoot from a neuroglia mass, with which they were originally connected, and from which later in the growth of the connective tissue they had become separated. Another possible explanation is that early in the development of the tumor a small group of neu-

roglia cells became separated in the midst of connective tissue elements, formed their specific intercellular substance and then disappeared. Either theory would explain their present position, assuming that they are true neuroglia fibers, that is, fibers formed by neuroglia cells. Of this we have no proof, except the morphology

Fig. 10—Early stage in formation of so-called rosette—a local thickening of epithelium of a cyst with formation of fibers between cells.

of the cell, the relation of the fiber to the cell and the staining reaction of the fiber. The former, in many cases, is by no means definite, and in this connection no cell resembling neuroglia cells are present. Doubt as to the latter arose from the following: In some of the teratoid tumors, in which no neuroglia occurs, there

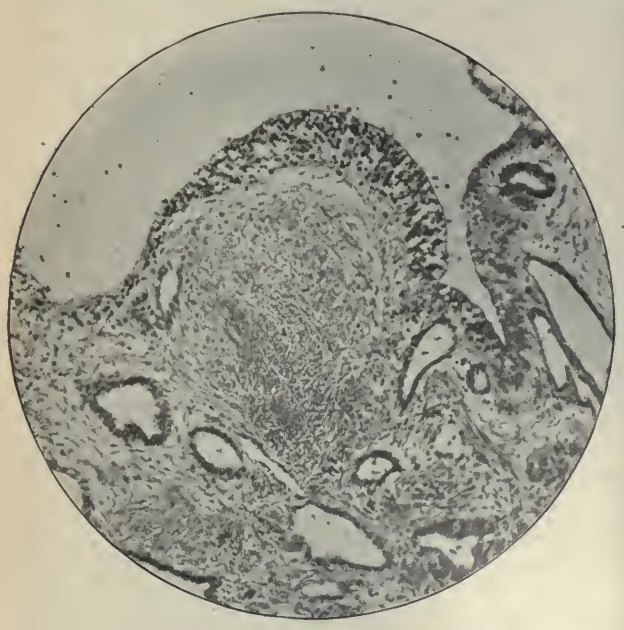

Fig. 11.—Beginning of pushing forward of epithelium by connective tissue formation at base.

are present about sweat ducts fibers staining in the same way as neuroglia fibers, with both the phosphotungstic acid hematoxylin and modified fibrin methods (Fig. 14). While these studies were in progress, Dr. Mallory, investigating connective tissue and smooth muscle, found fine fibers which stain red by the acid fuchsin potassium permanganate method, in sharp contrast to very abundant unstained fibers. This method also stains sharply true neuroglia fibers, and suggests a possible further resemblance in staining reaction between neuroglia and certain connective tissue fibrils.

To test this analogy three specimens of carcinoma of the breast, in whose stroma Dr. Mallory had found the red staining fibrils very abundant, were fixed in either formaldehyd or alcohol. To these were applied the phosphotungstic acid hematoxylin, modified fibrin, Benda's and Huber's methods of staining neuroglia. With all of these fibrils were found, which, from their holding the stain and, to a certain degree, their relation to cells, might be confused with neuroglia. From this it is evident that there are connective tissue fibers which do not readily decolorize after these staining methods and whose identification can not be based solely on staining reaction, since they at times stain in a manner similar to neuroglia fibers.

From this evidence it appears that the fibers scattered in the connective tissue of the teratoid tumor staining

Fig. 12.—More definite pedicle of connective tissue capped by mass composed of cells and fibers.

in the same way as neuroglia are not of necessity of neuroglia origin. Their true nature at present is indeterminate. In some places they are probably neuroglia, in others not.

Dots, staining in the same way as the neuroglia fibers, have been described as occurring in many of the cells of these tumors. The question as to their significance naturally arises. Similar dots or short rods have previously been described by Weigert in the normal ependyma,[8] by Storch in cells lining small spaces of a glioma,[9] by Benda,[10] by Mallory,[11] and by Lewy,[12] in the neuroglia cells of gliomata and by myself[3] in a teratoma (tu-

mor 1 of this report), both in the cells lining cysts and those scattered among neuroglia fibers. Various meanings have been attached to them. Weigert in his first paper regarded them as an interrupted cuticular layer. Mallory considered the dots as possible evidence of the ependymal origin of the gliomata studied by him. I,

Fig. 13.—Several ingrowths into a cyst.

concurring in this view, attached a similar import to their presence in a teratoma. Lewy looked on them as centrosomes, but regarded the presence of groups of them in neuroglia cells as an inheritance from ancestral ependymal cells, and the ring or rosette arrangement of some as a probable rudimentary cilia formation. In considering the different views, certain facts have been brought out which do not readily harmonize with them, though at the same time it has not been possible to determine definitely the nature and significance of these

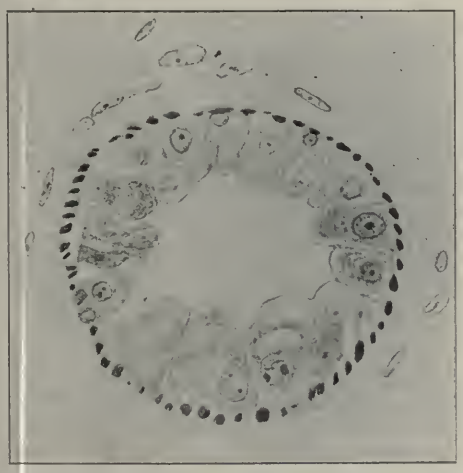

Fig. 14.—Sweat duct in teratoid tumor, showing cross section of coarse longitudinal fibers lying between true basement membrane and epithelial cells. These stain with neuroglia stains.

dots, and the attempt to advance any new hypothesis regarding them will not be made.

The earlier view of Weigert that they are a cuticular arrangement no longer seems tenable since the dots are found irregularly scattered through the cytoplasm of cells lying in the midst of large areas of neuroglia fibers and lining no space or lumen.

Are they centrosomes? They can be stained by methods used for demonstrating centrosomes as the iron hematoxylin method. Multiplicity of centrosomes has been described by Heidenhain in bone marrow giant cells. We have studied these dots in the ependyma of a series of pig fetuses from 18 mm. to 17½ cm. in length, and in several early human fetuses, using the phosphotungstic acid hematoxylin staining method. Here they are almost always present as a row or group adjacent to the spinal canal or ventricle. At this time nuclei are situated generally at some distance from the central space and its bordering dots, and dots are not found except in this arrangement. Mitoses of the cells in this region are common, and the dividing nuclei often approach near the space at whose border the dots are grouped. Yet there is no apparent change in the dots, nor are any dots seen associated with the mitoses. This does not seem to favor the view that the dots are centrosomes.

That they bear no close relation to the formation of neuroglia fibers, whose staining reactions they have, is shown by their presence in the fetuses studied at a time much before the fibers show any evidence of their presence.

The dots are already present in an 18 mm. pig, when, according to Hardesty,[13] differentially staining neuroglia fibers appear first in pigs from 16 cm. to 21 cm. in length.

The dots do not appear to be closely associated with cilia, since they were absent in some ciliated cells, and occurred in some non-ciliated cells. They are not always present in cells which originate from ciliated cells, as they could not be demonstrated in an adenocarcinoma of the uterus.

Can the presence of these dots be considered evidence of the ependymal character and ancestry of a cell? Dots were not found in most parts of these tumors except in neuroglia cells or cells lining cysts, and presumably of ependymal character. They were not found in several carcinomata of the breast or in a malignant adenoma of the large intestine. Dots very similar were found in the high cylindrical epithelium of that part of one tumor described as resembling a papillary adenocystoma of the ovary. Dots similar, but slightly larger, were found in some sweat ducts in these teratoid tumors and in those of a specimen of normal skin. Larger granules staining similarly with Mallory's phosphotungstic acid hematoxylin were found in the pancreas, but dots were not present in the kidney of this case, nor were they found in the fetal organs of the 18 mm. pig. This shows that dots, if not identical with those occurring in true ependyma, yet staining similarly, occur in cells undoubtedly of different nature, and so the mere presence of such dots in a cell or group of cells can not be considered diagnostic of the ependymal character and origin of these cells. When they do occur in cells which offer other evidence of a central nervous system origin, it seems justifiable to regard their presence as adding evidence in favor of the view that the cells containing them bear a genetic relation to ependyma. This is true for cells which line cysts and are in close relation to neuroglia tissue and for cells which are embedded in neuroglia fibers. Where the cells line cysts and bear no close relation to neuroglia, such a conclusion does not seem justified, and their nature remains undetermined.

13. Hardesty: The Neuroglia of the Spinal Cord of the Elephant with Some Preliminary Observations on the Development of Neuroglia Fibers, Am. Jour. of Anat., 1902, ii, 81.

CONCLUSIONS.

From the preceding work the following conclusions may apparently be drawn:

1. Neuroglia is a common constituent of teratoid tumors.

2. Its structure in them is very varied, simulating many known forms.

3. Neuroglia is more intimately associated with mesoblastic tissues in teratoid tumors than elsewhere.

4. In such tumors occur isolated fibers and groups of fibers which stain like neuroglia, but whose nature can not be determined by the staining reactions of Mallory. Huber and Benda, since these methods may stain other fibers than neuroglia fibers.

5. In many cells of these tumors occur small dots or groups of dots which have similar staining reactions to neuroglia fibers.

6. The presence of these dots in cells, though not absolutely diagnostic, may be considered as evidence in favor of the ependymal origin of the cells in which they occur.

Finally, it is with great pleasure that I acknowledge the very many valuable suggestions made by Dr. F. B. Mallory and his interest in this study. To Dr. J. A. Sampson of the gynecologic department of the Johns Hopkins University I am indebted for a number of these tumors, and to Dr. W. H. Lewis of the anatomic department of the same institution for the series of fetal pigs.

DISCUSSION.

DR. L. HEKTOEN, Chicago—Are the rosette bodies which you have described to be regarded as imperfectly developed eyes?

DR. H. A. CHRISTIAN, Boston—The analogy of these structures to eyes was considered and there is a great deal in favor of this view. The occurrence in many of these cysts of pigmented epithelium, the fibers which suggest Müller's fibers, and the small round nuclei which are very common in imperfectly formed retinæ, are all in favor of that theory; but there is no proof of what they are, and this is a mere opinion. However, I regard them as possibly an attempt to form eyes.

HEMOGLOBINURIC FEVER.

ITS CAUSES AND TREATMENT, WITH ESPECIAL REFERENCE TO THE USE OF QUINIA.*

WALTER SHROPSHIRE, M.D.
YOAKUM, TEXAS.

In presenting this subject for your consideration, we do so because of the diversity of opinion concerning it, hence evident need for more thorough study and discussion. Our consideration must leave out many of the features and characteristics of that arch mimic of all diseases, malaria, and be confined to that disease characterized by hemoglobin in the urine and due to malaria in some of her protean manifestations, discarding for the time Yersin's supposed discovery of a specific cause other than the malarial plasmodium, and all other theories and suppositions born of efforts to account for this peculiar manifestation.

In making an effort to clear up some of the uncertainty enveloping the subject, and to arrive at the truth concerning this disease, it was determined to depend, not alone on the individual conclusions of those who saw the disease, influenced no doubt by former teachings and impressions, but to get as thorough report of cases as possible, and view them, their cause, treatment and results, singly and collectively, drawing conclusions from recorded facts, and not by one individual or from one point of view, but by men of many localities, teachings and impressions.

Accordingly 2000 blanks for report of cases were printed, which provided for a thorough report of all features that we are to consider here, together with some others that are desired for future consideration, and with a letter requesting a report of cases were mailed to the physicians of southern and eastern Texas and Louisiana, selecting localities where it was presumed the disease most prevailed. Of those requested, 81 replied; 40 of whom could not report cases, while 41 reported 173 cases, to which I added 29 cases of my own, making a total of 202 cases reported by 42 observers. Many of those reporting had treated many times the number of cases reported, but owing to the lamentable fact that no case book was kept, they were unable to make even a partial report on others.

Of those cases reported many features of the disease were unreported on, owing to the fact that in most instances the patient was in the rural districts, so far from the attendant's office that frequent and proper observations could not be made; and when the patient was seen many of the accoutrements necessary for proper observation were not at hand. Therefore, in tabulating and reporting on the different features observed, it will not be of the whole 202 cases, but of that number on which these features were reported.

Of the 202 cases collected there were 61 cases treated without methylene blue or with less quinia than 15 grs. per diem, which is practically no quinia, of which 26.2 per cent. died and 73.8 per cent. recovered; while 112 were treated with 20 grs. or over of quinia, of which 16.9 per cent. died and 85.1 per cent. recovered; 4 were treated with methylene blue, with 1 death and 3 recoveries.

Of the cases treated without methylene blue or quinia 30 per cent. had hemorrhage from other organs than the kidneys, occurring on the second, third and fourth days, evidencing a non-subdued condition of the malaria and its recurrence, involving other organs; of these 50 per cent. died, two during the chill following the hemoglobinuric attack, and one during the second chill thereafter.

Of those treated with quinia, 9.8 per cent. were so affected, with 3.6 per cent. fatality. It thus appears that quinia effects not only a lower death rate, but also lessens the percentage of recurrent paroxysms. In those cases treated with quinia your attention is invited to the following facts which bear on the adequacy of the dosage: Of 50 cases treated with 20 to 30 grs. per os, 22 per cent. died; while of those given 30 grs. or over in the stomach, 16 per cent of the 43 died; and of those given 40 grs. or over only 8.6 per cent. of the 35 died. Of the 19 cases treated with quinia hypodermically, only one case or 5.26 per cent. died, and that one within 48 hours of the onset, of toxemia, due to the paroxysm had before treatment was begun. There were 12 cases reported where the urine became darker upon the administration of quinia and three where it became darker when quinia was withdrawn. Of the total of the non-quininized patients, 9.8 per cent. died of uremia, while of the 19 deaths among quinia patients, 8.9 per cent succumbed to uremia. While uremia occurred in 16 per cent. of those treated with less than 30 grs. by the stomach, it occurred in only 2.8 per cent. of those treated with 40 grs. or over by the stomach, and not at all in those treated with quinia hypodermically. The average illness of those treated without quinia was 9.66 days and of those

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

treated with quinia, 5 days. Of the men reporting on the point, 29.41 per cent. believe quinia may and does produce hemoglobinuria, while 70.59 per cent. believe that it does not. The largest dose of quinia that seemed to produce hemoglobinuria was 40 grs., while the largest which did not produce it was 100 grs. The average largest dose that seemed to produce hemoglobinuria was 13 grs., while the average largest dose that did not produce it was 52.6 grs. The smallest dose that seemed to produce hemoglobinuria was 4 grs. and the average 6.4 grs., while about 15 per cent. of cases occurred when no quinia had been given for 24 hours or over. The total average dose that seemed to produce hemoglobinuria was 9.7 grs. per day.

In each case here estimated, the subject had been living in a violently malarious locality three months or longer, and most of them for years. In all save one there was history of malarial paroxysms immediately preceding the pernicious or black water form, and in all a previous malarial development. The number of men reporting blood examinations was 4. Number of cases, 12; parasites found in 5 cases, not found in 7.

The following conclusions are justified:

1. This disease always occurs in persons suffering repeated attacks of malaria (this was so in every case reported).

2. It nearly always follows one or more mild paroxysms of malaria at the proper time for its next exacerbation (there was but one exception to this reported).

3. It has all the characteristics of malaria, chill, fever and sweat.

4. Where adequate examination of blood is made, the hematozoa of malaria are found (it was so in 41 per cent.).

5. Its habitat, that of most violently malarious districts (all cases reported were so) are sufficient to establish malaria as a causative agent, if not the only one.

To the present there is no claim for a cause other than malaria worth more than a passing notice, except the one which is maintained by about 30 per cent. of those reporting, namely, that quinia produces it, to which claim we invite your careful and scrutinizing attention.

To establish the cause of any disease we must apply the agent to the subject and have, as uniform result, the disease. But if there are two agents suspected as causative which applied together produce the disease, but applied separately to the same individual the one produces it, the other never, we can attribute only to the one a causative place and to the other an accidental presence.

Such is the case before us. Malaria, taken as a cause and applied without quinia to an individual of such tendency, hemoglobinuria results in 15 per cent. of the cases before us. Quinia had been applied to probably all of the cases before us without the presence of malaria and no hemoglobin appeared in the urine. Then in 85 per cent. of them malaria and quinia were both applied to the individuals, hemoglobinuria resulting. Which produces it?

Physiologically quinia acts on the blood, nerves and small vessels. On the blood it inhibits the oxygen-carrying power without causing separation of the hemoglobin from the corpuscle. On the nerves it is, first, a stimulant, then as the dose increases a depressant till it suspends the function of some of them entirely, as the optic and auditory, and in lethal doses, those governing the heart.

On the blood vessels it acts as a vasoconstrictor, increasing blood pressure and toning up those areas where from malarial toxemia there is a stasis, as in the brain in some forms, and the gastro-intestinal tract in others, and in the case before us, in the kidneys. And, like all such remedies, when increased sufficiently it ceases to act as a stimulant to the vasoconstrictor muscles and acts as a paralyzant of them, hence a dilator of the vessels, this occurring just as the lethal dose is reached, which, added to the suspending of the function of the vagus, causes such lowered blood pressure that death soon ensues.

Reviewing these effects of quinia it is indeed difficult, if not impossible, to conclude logically that it can produce hemoglobinuria. To consider it from an experimental standpoint, we observe that the deaths produced by quinia have been due to its effects on the nervous and circulatory systems, with never an occurrence of hemoglobinuria. If quinia is capable of producing this condition at all, it looks strange that lethal doses have never produced it, while those who believe it capable of doing so attribute the production to an average daily dose of 9.7 grs. Thirty of the cases before us had the disease without the exhibition of quinia and of those who were taking quinia when the hemoglobinuria developed, in 89 of the 108 under increased dosage it disappeared. Indeed, it appears to me that one must be a fit subject for homeopathy to conclude that quinia, having produced the disease in 108 cases, would cure it in increased dosage in 89 of them. Again, in those where quinin might be supposed to produce the disease it were untenable logic to maintain that removing the cause would result in an increased death rate, while increasing the cause would diminish it, as 26.2 per cent. is to 16.9 per cent.

Of those reporting, the maximum dose of quinia given without producing hemoglobinuria, the largest dose was 100 grs., and the average 52.6 grs., and of those reporting the largest and the smallest dose that seemed to cause hemoglobinuria, the largest dose was 40 grs. and the smallest 4 grs., or an average of 9.7 grs. per day. Now, in the face of reason, can we maintain that 9.7 grs. of quinia will produce the condition when 52.6 grs. fail to produce it?

Those cases where quinia has seemed to produce hemoglobinuria have invariably been in persons known to be malarially infected, where the disease seemed mild and quinia was administered to eradicate it. Carefully considering these cases, we will note that of 1000 cases so treated probably in 950 cases the disease disappears, one develops the hemoglobinuric form, one the comatose form, three the enteric form, while 45 will return still in the mild form. There is unquestionably as great a percentage that develops the comatose form, due to peculiar determination of the disease to the brain, and three times as great a per cent. that develops the enteric form, due to the determination of the disease to the intestinal tract, as there is of the hemoglobinuric form. Now, if the quinia produced the hemoglobinuric type, did it not also produce the comatose and enteric forms? And how about the 45 returns of the mild form? Did quinia produce them also? Is it not as rational to attribute the one to quinia as the other? Or is it not a fact that in all of the cases which recurred, the remedy had failed to effect the cure and the disease continued, in some assuming a more pernicious form, in others continuing the mild type? It appears that such is the case and that its assuming certain forms as it grows severer or its selections of certain organs on which to exercise its severest toxic effect, is one of individuality or peculiarity of the subject and not of the remedy. If quinia is to be eschewed in treating the one form, hemoglobi-

nuric, should it not be shunned in the others, comatose and enteric? Yet I dare say that no man in this assembly would have the temerity to withhold quinia, the only specific, in the comatose or other pernicious forms of malaria.

Another strong evidence that it is the individual peculiarity that determines the hemoglobinuric form, is the fact that this form recurs again and again in the same individual and is prone to run in families, while seldom indeed an individual who has suffered an attack of hemoglobinuria develops a pernicious malarial attack other than the hemoglobinuric form. Why is it thus, if not due to the individual peculiarity?

Another error in the conclusion that quinia produces hemoglobinuria is the fact that in the vast majority of those cases quinia is withheld during the greatest pyrexia of the preceding attack, or to wait the action of calomel, and is administered too late to prevent the pending paroxysm; this growing more severe assumes the hemoglobinuric form, or, if it has already become hemoglobinuric, the urine that has partially cleared during the interval becomes darker, which is attributed to quinia. In this connection permit me to say that in every case seen where quinia had been administered and might be supposed to play a part in producing hemoglobinuria, the paroxysm occurred at the regular time for the exacerbation of fever and with chill and rise of temperature, just as occurs when the disease is left to malaria alone; and in those cases reported by others, even where black water occurred as often as three times, the increased color of the urine marked well the time for recurrence of malarial paroxysm in approximately 20 per cent. occurring on alternate days, 75 per cent. on successive days and 5 per cent. twice daily, just as we find malaria acting in other forms than this.

Bearing in mind the established fact that the malarial parasite is most easily killed by quinia in its younger existence, it is easy to understand that withholding the drug through the stage of high fever or till the effect of calomel is had, will permit the growth of the plasmodium to such a size as to be decidedly more resistant to quinia, and to allow it to go on to sporulation, thus producing another paroxysm which may be pernicious, even hemoglobinuric, and still there be enough quinia in the blood to kill the young parasite as it is set free in the plasma, thus explaining some of the spontaneous cures without further administration of the drug.

Another error in quinin therapy of this disease, to which your especial attention is invited, is inadequate dosing. The estivoautumnal parasite, the one most commonly producing this disease, is far more resistant to quinia than other forms, and it, like all forms of animal life, becomes habituated to any poison till it can withstand even ten times the dose necessary to kill when not so habituated. In all violently malarious districts, such as this disease prevails in, and especially in every chronic malarial subject, there is, without exception, in this country, a partial saturation of quinia for a considerable time, if not by quinia prescribed as such, then by quinia in the form of the numerous patent chill tonics, which have for their base quinia; hence the malarial plasmodium in this disease has, to some extent, become a quinin habitué, and only vastly increased doses prove toxic. Personally this has been observed many times; in one instance, 25 grs., given hypodermically to a year old child suffering from the enteric form, although administered 8 to 20 hours prior to the pending paroxysm, failed to prevent it and the little fellow died during the chill. You will observe that only 8.6 per cent. died where the dose was 40 grs. and over, while 22 per cent. died with 30 grs. or less.

Your attention is called to another point of error in quinin therapy in other forms of malaria as well as this, and it is by far the most important point of all—that of failing to get the drug into the blood. It is adequately proven and generally conceded that the malarial parasite destroys its host, the red blood cell, on sporulation, thereby setting free into the plasma what hemoglobin it has not consumed, there to remain until the liver has converted it into bilirubin. This, frequently repeated and in excessive quantities in the pernicious types, overwhelms the liver with work till its function is almost, if not quite, suspended, and a stagnant portal circulation results, hence the *vis-a-fronte* causes a passive congestion of the stomach mucous membrane and a cessation of its functions, both secretory as to hydrochloric acid and absorptive. The first of these conditions evidenced by alkaline vomitus, would prevent the solution and absorption of quinia put in the stomach in other than an acid solution, were we able to keep it there, while the abolition of the absorptive function would prevent the taking of quinia into the blood were we able to maintain an acid solution on the stomach; or more accurately speaking, the blocked portal circulation would prevent its entrance to the general circulation and its application to the parasite. So quinin dosage by the stomach is in many instances but a method of deceiving ourselves in the belief that we have applied this specific in a case where it is needed, while in fact the drug has never reached the blood where the parasite lives.

Just here your attention is called to the fact that all the cases where quinia was thought to be the cause of hemoglobinuria have been cases where it was given by the stomach and by men who depend on the stomach administration, while not a case receiving hypodermic administration developed the disease and none of the men who depend on the hypodermic method attribute the disease to quinia; the death rate under the hypodermic method being 5.2 per cent., while that under stomach administration is 20 per cent. This, taken in connection with doubtful ability to saturate the blood through the stomach in pernicious forms, seems quite significant.

It is claimed that hemoglobinuria is the manifestation of an idiosyncrasy for quinia. Yet no case of unquestioned freedom from malaria has been observed to develop hemoglobinuria from quinin administration, and in every case observed and reported the patient had taken quinia for other troubles and mild forms of malaria without the development of hemoglobinuria. If quinia produces it in severely malarial subjects, why not in mild and non-malarial ones?

Those cases attributed to quinia are not experimentally produced or based on physiologic or pathologic facts, but on purely paracelsian empiricism. Are we justified in adopting this method of reckoning against such preponderating evidence to the contrary in this age of enlightened and logical therapy?

The commonly accepted symptoms of cinchonism may and do cause us to err in our efforts to cinchonize our patients by the stomach, for of tinnitus aurium, nausea, relaxed and moist skin, dilated pupils, generally accepted as indicating quinia in the blood, the two former are most depended on and least reliable. In fact, I do not believe them due to quinia in the blood at all, but to the application of quinia to the end organs of the

nerves in the stomach mucous membrane. They are like the urticaria due to gastric irritation, a manifestation of the irritation of those nerves by quinia. Not infrequently violent complaint of those symptoms has been made during the stomach administration of quinia and by changing to the hypodermic method, even with an increased dose, the complaint has ceased. You will pardon a brief report of a case in this connection which illustrates the fact. Mrs. C., a malarial cachectic of repeated recurrent attacks during the last 12 months, was suffering quotidian malarial paroxysm. Quinia sul. was prescribed morning and night in gram doses after Koch's method. The paroxysm occurred next day at the usual hour. Quinia was increased to three grams daily; the next morning the paroxysm was on time and hemoglobinuric. She was complaining vehemently of cinchonism and insisted that no more quinin be given, as it was doing no good, and making her sick. Now, one who in the least feared quinia as a cause of hemoglobinuria would have discontinued it when the disease assumed the hemoglobinuric form under 45 gr. doses, but the method of administration was changed to hypodermic and 20 grs. given every 4 hours, or 100 grs. per day, and the symptoms of cinchonism largely disappeared, the urine cleared, and the patient made rapid recovery.

In this case, as in several others equally as emphatic, the symptoms of cinchonism complained of disappeared under the increased dosage when the drug was removed from the mucous membrane of the stomach, and what some would have considered hemoglobinuria produced by quinia, disappeared under vastly increased doses when it was put directly into the blood. The only rational conclusions to be drawn from such cases are, first, the quinin applied to the gastric mucosa produced the symptoms called cinchonism and that its removal permitted the symptoms to subside; second, that the quinia had never been absorbed and carried into the blood, and therefore had not killed the parasite, whose ravages continued till quinia was so applied and terminated their career.

Summing up the evidence for and against quinia as a cause for this disease, we have:

Of the physicians reporting, 29.4 per cent. affirm it.	Of the physicians reporting, 70.59 per cent. deny it.
When quinia is suspended in treatment, 73.8 per cent. recovered.	When quinia is administered 83.1 per cent. recovered.
Distinct recurrences of attacks after the first appearance of black water in non-quininized patients, 9.8 per cent.	Distinct recurrences of attacks after the first appearance of black water in quininized patients, 4.4 per cent.
Per cent. of cases occurring from quinin alone, no per cent.	Per cent. of cases occurring from malaria without quinin, 15 per cent.
Per cent. of cases where quinin was thought to aggravate, 5.9 per cent.	Per cent. of cases where quinin was thought not to aggravate, 55.4 per cent.

With such preponderating evidence against quinia as a causative agent, that portion of the subject is left with you.

TREATMENT.

In taking up the treatment of this disease I shall be as brief as possible, giving the greater time, first, to those methods on which we differ; second, to those thought most important; third, those not in common use—dwelling but little on those measures of common acceptance and usage among us.

The inter-relation of cause and treatment, or the dependency of the one on the other, has caused in considering the first the foreshadowing of the most important feature of this portion of our subject. If the disease is due in part or whole to malaria, the treatment should be to remove the cause by administering quinia, the specific, in a manner sure to reach the parasite in the blood, and in sufficient dose to kill with certainty.

In dangerous diseases like this we should never reverse the order of the old Latin maxim, *"curare, cito et jucunde." "Curare"* should stand first; and in selecting methods of administration the one surest to carry the remedy to the parts desired should without exception be our choice, so long as imminent danger to life is not incurred—hence, intravenous or hypodermic administration should be resorted to in medicating a patient suffering from this trouble.

In dosage of quinia one should steer well on the side of the drug, remembering that the parasite is of that type most resistant to quinia, and as a rule has become to some extent habituated to the drug. Bearing these facts in mind and taking for our base the dose that ordinarily proves efficient in other forms of malaria, an average of 30 grs. daily, we would take for an average dose in this condition, 40 grs. intravenously or hypodermically per day, until the next period for an exacerbation is safely passed, and continue it in half that dose until the second expected exacerbation is safely passed, when it should be discontinued for three or four days, and repeated in 20 to 30 grain doses every four to six days till five or six weeks are passed without a paroxysm. In the primary administration of the remedy one should remember that the older the parasite the greater its resistant power to quinia; therefore the sooner it is administered after the parasite has sporulated (the onset of the paroxysm) the easier it is killed and the surer is one to prevent the next paroxysm, which in pernicious malaria frequently means death to the patient.

Since Ivanoff,[1] by a careful study of the effects of quinia and methylene blue on the malarial parasite, has proven that quinia has its greatest affinity or toxic effect for the chromatin or nucleus of the plasmodium, which constitutes nearly the whole of it soon after hatching, and loses it as the achromatic zone accumulates around the nucleus as the parasite grows older and larger (a fact well proven clinically long since); and that methylene blue has greatest affinity for the achromatic zone (nicely portrayed by Romanovsky's method of staining), it behooves us to remember methylene blue in cases where we are called so late that quinia alone might fail to prevent the pending paroxysm, and to combine then the methylene blue in 3 to 6 grs. doses, two or three times daily. Another characteristic of methylene blue that recommends it in these cases is its sedative effect on the nervous system as portrayed by Hughes and Lovelace,[2] where of 22 cases of acute mania treated with it 16 received natural refreshing sleep. Of four cases of this disease reported treated by methylene blue there were three cases, or 75 per cent. recovered. Of the 19 cases reported treated with quinia hypodermically only one death is reported, and that occurred within 48 hours, showing that it was the result of the paroxysm had prior to any treatment, and not after quinia or any other remedy might have prevented it.

The tardiness of the effect of arsenic as an antiperiodic practically puts it out of consideration in conditions so pernicious, and its tendency to irritation of the renal epithelium also contraindicates it. There is no other drug whose mention in this connection is worthy of our time.

Considering other conditions for treatment, the inactivity of the liver stands first and a cholagogue is certainly indicated, for the presence of free hemoglobin in

1. Deutsche Med. Wochenschrift, May 2, 1901.
2. Phila. Med. Jour., March 22, 1902.

the plasma would alone, if undisturbed, soon prove fatal, to say nothing of the stagnant portal circulation obstructing nutrition and medication intended to alleviate other conditions. Calomel is certainly one of the best, if not the best, cholagogue and its inoffensiveness to the mucous membrane of the stomach commends it highly in this trouble where nausea is a predominating feature, hence calomel in small doses, often repeated (¼ gr. every half hour) is a favorite and justly so, and I would add 1-20 gr. of hyd. bichlorid hypodermically every five hours till the liver is well aroused, with massage of the liver or mustard plasters over it to the point of thorough redness of the skin. Of the 200 cases reported all save one were treated with calomel as a cholagogue and I note that the greater one's experience with this disease the more urgent is his advocacy of calomel.

Certainly to unload all effete material from the bowels and stimulate their eliminative function would add to the chances of our patient, and enemas of hot solutions of sulphate of magnesium accomplish this quickest and surely, together with stimulating diaphoresis, a valuable means of eliminating much undesirable material from the blood and relieving the irritated kidneys of some tax. To allay the nausea and vomiting, iced champagne has proven most efficient in my hands, with ice cold beer a close second, the former adding stimulation and the latter both stimulation and diuretic effect to its credit. While large drafts of very hot water have often proven very efficacious as a stomach sedative, as well as a diaphoretic and stimulant, one of my advisers strongly urges this as the most important treatment of all. So soon as the stomach is in a condition to appropriate it, nutritious fluid food should be given at regular and proper intervals. For the kidneys, hot fomentations over the loins or perhaps counter-irritants with mild diuretics should be given, every effort being made to save the kidneys any irritation and labor. The intravenous injection of large quantities of normal salt solution serves well to stimulate over the depression, and assists in eliminating poisons from the blood, and in one case reported, where entire suppression of urine had occurred, it started up the renal secretions and the patient recovered when apparently he was doomed. Stimulants and tonics hypodermically in liberal doses should be used to maintain the vital functions, and here strychnia stands first. So soon as the expected paroxysms are safely passed, ferruginous and bitter tonics per os are to be given, steam baths and sweat baths are recommended and have to commend them the greatest relief of the kidneys by their diaphoretic action.

The time and space required to enumerate writers and practitioners who have assisted in these efforts are too great to allow their recital, hence the omission of a bibliography.

DISCUSSION.

DR. WILLIAM KRAUSS, Memphis, Tenn.—One can not study diseases by any rules of logic, but we can discuss that way. The reader of the paper states that, among about 170 cases reported, the blood examination was made in 12, and 7 of these 12 did not show the malarial parasites; if that were so, I should like to know why he cinchonized these 7 patients? About 12

years ago I attempted, by proxy, to study this disease and found in a very short time that it was exceedingly unsatisfactory. Then I attempted to place myself in touch with gentlemen in the vicinity of Memphis, requesting them to wire me when they had such cases and I would take the first train to them. This also proved to be unsatisfactory. I then decided to abide my time until I could get a visiting service in a local hospital where I could study the disease properly from beginning to end. I think it is illogical to attempt to classify the mortality according to the treatment, irrespective of the pathologic conditions; whatever remedy we use should be given to overcome the pathologic conditions or to remove the etiologic factors which may be present in a given case. Judging from the character of the cases reported he evidently saw cases of the intermittent variety, accompanied by chills and fever, and such cases are exceedingly rare during the season of the estivo-autumnal parasites. They are found in the spring and early summer and are very transient. In his cases he found the parasites persisting through the attack. It is proper to cinchonize such cases.

What is the pathologic condition to be found in such cases? It is a steatosis of the kidneys and liver, a rapid breaking down, and, if present, a disappearance of the malarial parasites. The treatment must be directed to that end. What is the pathology of the blood? There is a hemolysis. If you have studied the subject of hemolysis only very superficially you

know that it requires a specific immune body and a complement to produce it. The normal mechanism of this in malarial infection is probably for the destruction of infected red blood cells. There is a later storage of a surplus of this specific body; the complement may be produced either by quinin or a new superadded infection—either, then, may be the occasion of an attack. This is where the question of administration or non-administration of quinin comes in. In the majority of the cases the hemolysis effects the destruction of the parasites. The subsequent temperature may be a guide; as a rule, the present malarial infection may be ignored. The doctor has stated that only small doses of quinin produce the hemoglobinuric fever, and in one case he produced it with 90 grains; if that is a small dose I should like to know what he considers a large dose.

Last summer, during my illness, there were admitted to St. Joseph's Hospital 21 cases of malarial hemoglobinuria, and all were treated with hypodermic injections of quinin; two recovered. On the other hand, I have now an unbroken series of 21 cases without a death. The main point is, avoid cinchonizing these patients. Take such measures as you can to prevent fatty changes taking place.

DR. FRANK A. JONES, Memphis, Tenn.—A few days ago I heard Dr. Osler say: "Tuberculosis is the captain of the men of death." I should like to paraphrase that expression, and say: "Tuberculosis is the captain of death and malaria is his first lieutenant."

We have in our midst to-day a quartet of men who have been working in malaria. One of these is Dr. Krauss, and there is no man in this country who understands malaria better than he. Then we have among us another gentleman whom we all know and greatly respect, and who has written a book on malaria; I refer to our chairmain, Dr. W. S. Thayer. Again, we have another gentleman of brawn who has been brought up in a country district, at a little flag station, but yet who has the best equipped laboratory in Mississippi; I refer to our secretary, Dr. James B. McElroy. One is a wheelhorse; the other an Ajax. Then, too, I ask that Dr. Sutherland of Mississippi, another man who has done much on this subject and a man whom all greatly respect, be asked to address this Section.

DR. H. L. SUTHERLAND, Rosedale, Miss.—This subject has been frequently discussed and the principal feature of discussion always is as to the advisability of the use of quinin. I think there is one proposition on which we all agree, namely, that in the presence of an active estivo-autumnal infection we should use quinin. It seems to be the general opinion that "the existence of the hemoglobinuria itself, or the presence of some other toxic substance in the blood" (Thayer) destroys the parasites and renders the administration of quinin unnecessary and therefore harmful; but, in my observation, this is not always true. The use of the microscope should then govern, in these cases, the use of quinin. But, unfortunately, only a very small percentage of physicians practicing in sections where hemoglobinuria occurs have a practical knowledge of the use of the microscope, and therefore must find some other method of determining the treatment.

After the appearance of hemoglobinuria, my first attention is directed to elimination, and I do not give quinin in the first twenty-four hours; if the fever continues high, I give 15 or 20 grains of quinin or two ounces of Warburg's tincture. If the patient has taken quinin preceding the attack, I am not in a hurry to give more, but rather await the result of what he has taken. I can better illustrate by citing two cases in point: In August, 1901, I saw a case with a temperature of 101, and next day 102, and the third day 104.8, when I gave two ounces of Warburg's tincture, and his temperature dropped to 101. I repeated the dose and his temperature became normal, and on the fifth day of the disease there were a few estivo-autumnal organisms present.

Oct. 25, 1902, my son had a chill and in the next forty-eight hours took 48 grains of quinin. Several hours after the last dose he had a chill with fever, which soon subsided and I gave no more quinin; in thirty hours after the last dose of quinin he had another chill with hemoglobinuria, but his temperature did not go over 102, and in another twenty-four hours his urine had cleared and temperature was normal. I supposed he had had sufficient quinin prior to the hemoglobinuric attack to kill the malarial organisms. A blood examination made by Dr. Krauss of Memphis, October 31, showed "very active estivo-autumnal infection," and I began the administration of quinin again. These two cases prove, to my mind, that in some cases at least quinin should be given, while, perhaps, in a majority of cases, they get along better without it; and I have adopted the rule that where the fever following hemoglobinuria continues high after tewnty-four hours, or from a temperature as low as 101, its tendency is to go higher each succeeding day, I give quinin, and following this rule I find I give it in about half of my cases.

DR. JAMES B. MCELROY, Stovall, Miss.—I agree with the reader of the paper in the statement that hemoglobinuric fever is, in the majority of cases, due to malarial infection. That parasites are not always found in the peripheral circulation is due to several circumstances. Stephens and Christopher think it is due mainly to the fact that quinin has usually been administered previous to the occurrence of black water. This is undoubtedly true, but I have seen at least one case in which parasites were present previous to the attack; no quinin was administered previous to nor during the course of the disease, and the parasites disappeared a few hours after the onset. I have surmised that this is due to the fact that in the extreme hemolysis which takes place the cells of low resistance will naturally be the first to be destroyed, consequently the cells containing parasites are usually first destroyed. The parasites, being set free in the plasma, soon die.

I have observed more than fifty cases of this disease and in 19 cases have made repeated blood examinations. In only 5 of these have parasites been present, estivo-autumnal in 4 and double tertian in 1. The malarial nature of the remaining 14 was demonstrated by the leucocytic variation and pigmentation characteristic of malaria, and by the character of the febrile attack previous to the development of black water.

As to the relation of quinin to hemoglobinuric fever, in a few instances black-water fever develops in the course of a malarial infection in which no quinin has been administered, as in the case just referred to. But in the majority of cases it occurs in the course of an old malarial infection in which quinin has been administered. And my experience is in accord with the findings of the malaria commission to the royal society, which concludes that black-water fever is of malarial origin, but that it is not a malarial attack *per se;* that in the majority of cases quinin is the immediate causative agency. I have never seen a pure quinin hemoglobinuria, though it undoubtedly has occurred.

The few experiments which have been made *in vitro* to determine the hemolytic effect of quinin in these cases have, so far as I know, been negative. Recently I have been making some experiments along this line which, though limited, indicate that quinin has a hemolytic action on the blood of these cases.

As to treatment, occasionally in cases of intermittent hemoglobinuria—and I may say that such cases are comparatively rare in my experience—quinin used cautiously may be of benefit. But as a rule in the cases of continuous hemoglobinuria I do not think that quinin should be administered. In the first place, it is not indicated, as the parasites are not usually present, and when present its administration has aggravated the condition in my experience, as the two following cases will show: In the first case of the series of the 19 cases referred to above, parasites were observed during the course of the disease, on the third day when the urine had begun to clear. Following Bastianelli's rule, I determined to administer quinin. Seven and a half grains were given hypodermatically and four grains ordered per os every four hours. Two hours after the first dose the urine became black, suppression and death following during the night. Whether this was due to the sporulation of a new group of parasites or to the quinin administered, I am unable to say.

In case number ten of the series, parasites were observed during the course of the first day of black water when the

urine was clearing. Quinin was administered and a few hours afterward black water returned with an aggravation of all the symptoms. Quinin was immediately discontinued, and the patient recovered.

Dr. W. S. Thayer, Baltimore—There is little of value that I can say which has not already been said by those who have had much more experience with this condition than I. Hemoglobinuric fever does not occur in Baltimore. Those cases that I have seen I have visited at distant points—in Virginia, Tennessee and North Carolina. My knowledge on the subject has been obtained mainly from literature. One should remember that hemoglobinuria is not a symptom proper of malaria; it is a condition for which malaria opens the way; its remarkable limitation to special malarial districts is also well known. But one should further remember that hemoglobinuria occurs as well in a variety of other infectious diseases. It may complicate typhoid fever, yellow fever or smallpox. In malaria it may occur at the height of an acute paroxysm when parasites are present in the circulation. In many cases, however, the malarial attacks disappear on the first outbreak of hemoglobinuria, and parasites can no longer be found in the blood. Again, the condition occurs in patients who have recovered for a greater or less length of time from their acute malaria and are in a condition of postmalarial cachexia. This is often the case. In certain parts of this country the disease is met with more frequently in the late fall, at about the time of the beginning of frosts. I believe that it is fair to state that, in the majority of cases, within twenty-four hours of the onset of the attack of hemoglobinuria, the parasites of malaria are not to be found in the blood. If the case, however, be left to itself relapses of the malaria will follow sooner or later in many instances.

Quinin is of no more value in the treatment of the hemoglobinuria as such which occurs in connection with malaria than it would be in hemoglobinuria connected with such diseases as yellow fever or typhoid fever or smallpox. Quinin is of value in removing the ultimate cause—the malarial parasite; it is of no value in the treatment of the immediate conditions on which the hemoglobinuria depends. If the parasites do not disappear from the blood it seems to me that we are bound to administer quinin. If, in a given case, one suspects that the patient has pernicious malaria and microscopic examination of the blood is impossible, quinin should certainly be given at the onset of the trouble. If, however, after twenty-four hours no parasites are present in the blood it may be better to postpone quinin treatment until later.

With regard to the deleterious effects of quinin: True quinin hemoglobinuria must be of the greatest rarity in this country. Cases have been reported, especially in Sicily, in which the most minute doses of quinin have produced violent attacks of hemoglobinuria, cases in which there can be no doubt as to the nature of the condition. These instances depend probably on individual susceptibility.

With regard to the method of administration of the drug it is hardly worth while to speak. Quinin acts most promptly when given intravenously, and the dihydrochlorate gives excellent results when thus administered.

Dr. Walter Shropshire, Yoakum, Texas—With regard to the assertion by Dr. Krauss that I studied hemoglobinuria by proxy, I want to say that no one examined these cases but myself. I reported 29 cases in the series, and I had some I did not include because many of them were rather indefinite—I could not give in them a fair and honest consideration of the subject. Among the 29 cases there were but 2 deaths. In one of these a physician asked me to attend a patient for him, but refused to allow me to treat the case in my own way. This patient had a mild paroxysm every morning for three mornings and then hemoglobinuria. I had promised this physician to give the patient calomel and withhold quinin until it acted. I saw this patient at 4 p. m. one day and I realized the mistake in giving him calomel and not quinin till after it acted, for scarce time for the calomel to act remained before the next paroxysm was due, but I had promised to treat the case according to the physician's expressed wishes, and I gave him calomel. Of course it did not prevent the next paroxysm. When I returned home I asked that physician never to send me to another of his cases instructed. The next morning this patient had another paroxysm, entire suppression of urine and a fatal end followed.

The other fatal case was one in which there was a distinct nephritis present. He died on the sixth or eighth day in spite of the use of quinin. Thus out of 29 cases only 2 deaths were recorded, and one due to the non-use of quinia.

The pathology of the disease has been overlooked. Ewing reports examinations of kidneys after death in one case, and he said he was unable to find or demonstrate the parasite in the peripheral circulation, but at autopsy the kidney capillaries were found to be filled with them. In every case at autopsy in the pernicious form the parasites are found in the spleen and the brain in comatose forms, and stomach and intestines in the choleric or enteric forms.

If the parasites are to be found congregated in such situations in forms when symptoms are referable to it, why not in the kidneys in this form? The fact is they have been where autopsy was had and adequate examination made in reference to the non-appearance of the parasites in the peripheral blood. I should like to refer the secretary to one of his own cases, where it was found on the third day that the peripheral blood contained them after repeated negative examination. It has been noted that in the pernicious form of the fever the parasite seems to leave the peripheral circulation and invades the central circulation and organs, hence we can not depend on examination of the blood from the peripheral circulation as a guide to our therapy in this form of disease.

New Appliance.

AN EASILY DETACHABLE PLASTER-OF-PARIS CAST.

CHARLES O. BECHTOL, A.B., M.D.
CHICAGO.

It is the purpose of this paper to present a method of applying plaster of paris to fractured limbs which we believe to be new. The earlier idea of good treatment for a fracture was absolute immobilization. This was brought about by splints made of numerous materials and by bandages made stiff with various substances, i. e., white of egg, starch, and dextrin. Plaster of paris was first used for this purpose in Spain, but Kluge of Berlin, in 1829, first made a careful study of the application of plaster to fractures. This method of complete, long immobility of a part, accompanied sometimes by a too tight bandage, brought occasional loss of limb, constant stiffness of neighboring joints and atrophy of muscles and numerous unfavorable and unpleasant conditions.

The most radical departure from the old methods is expressed by Lucas Championnière in his "Traitement des Fractures par le Massage et la Mobilization" and by his followers. They believe that complete immobilization only prevents the first pain and friction of the broken ends of bone; that it imperfectly restores form; that subsequent swelling may reproduce deformity and that it does not favor callous formation or bony union. M. Canay proved that the broken bones of a dog if absolutely immobile would not unite and that human ribs, which can not be put entirely at rest, are the quickest to heal of any bones of the body. The treatment of fractures with massage and mobilization is limited to those cases which are not compound, have no large blebs and which have no great mobility or tendency of the deformity to recur. Its field is evidently narrow even if the patient could be under close enough observation to make its application possible.

The ideal treatment comprehends the best of each of these two widely different methods, i. e., absolute immobility during a part of the time to insure perfect position of the ends of the bones and normal lines and the ability to quickly remove an absolutely immobilizing apparatus that the parts may be inspected, massaged, hot water be applied and passive motion performed. A home-made splint requires more time in

the making and in the application than a good cast and it is at best an awkward, unsightly thing, which is constantly working out of place. The fracture-box requires the patient to remain in bed and is used now only in cases where the swelling is unusual or large blebs are present. Factory-made splints never fit. There is a class of perfect-fitting, detachable splints, made by impregnating layers of cloth with plaster cream, which approaches perfection. Some of these are applied anteriorly, some posteriorly and still others used as side splints and held in position by a roller bandage. The best of this class is the Bavarian splint, but it, like the others of its class, is objectionable because of the time consumed in

Figure 1.

the making (at least one hour) and the amount of plaster scattered about.

The author's cast was designed while he was a house physician at Alexian Brothers' Hospital, Chicago. It was used satisfactorily by him on about forty cases and is still being used by his successors. This cast is applicable to any part of an extremity where a splint or a cast can be used.

Figure 2.

For convenience a cast for Pott's fracture is described. The foot and leg are covered with a stocking or sheet cotton and a Gigli wire saw applied in the median line, anteriorly and posteriorly—these to be held in place by an assistant who also holds the fractured leg in the proper position. (Fig. 1.)

A few turns of the plaster bandage are then taken around the leg to hold the saws in place. A third saw is then applied along the sole of the foot and secured by a few turns of the bandage. (Fig. 2.)

The assistant can now busy himself with keeping the parts in proper position and alignment. The cast is then completed by applying successive turns of the plaster bandage, rubbing each turn smooth until it is in the closest possible contact with the one directly under it. It is well to make this cast a little thicker than the ordinary circular cast and care is necessary to make the portion over the foot and around the heel of equal strength as the rest of the cast. The only precaution necessary is to keep both ends of each saw free and avoid bending the saws at a sharp angle.

By the time the last bandage has been put on and the cast made smooth by rubbing with the flat of the hand, it will be hard enough to saw off. It need not be dry. A suitable handle or a small nail is attached to the loop in the end of the Gigli saw and by pulling the saw steadily until it moves freely the cast can be cut through in about ten seconds, leaving

Figure 3.

two straight edges. Fig. 3 shows the second stroke of the saw. The posterior and foot saws are removed in a similar manner and an ordinary roller bandage is put around the cast while it is still in position on the leg to hold the two halves together.

Figure 4.

If a stocking is used it must be split with a pair of scissors along the saw cut before the cast is removed and it then forms a good lining. If sheet cotton is used the leg should be covered by a new layer before reapplying the cast to take up the space occupied by the old cotton and form a comfortable lining.

This cast meets all the requirements of the modern treatment of fractures and has the double advantage of ease and rapidity of both application and removal. It is especially suited to Colles' fracture, because of the ease with which such a perfect-fitting splint can be made and the readiness with which it can be removed for inspection, massage and hot applications.

STREPTOCOCCI AND THEIR RELATION TO SPECIFIC DISEASES.

When bacteriologic methods were first applied to the systematic study of human diseases, it was soon learned that streptococci were widely distributed in connection with various morbid processes. Control investigations in connection with normal individuals showed them to be also commonly, if not constantly, present on various mucous surfaces of the body, especially those of the mouth and throat. When more exact bacteriologic methods had been elaborated and the streptococci, which were isolated by the plate method, were studied as to their tinctorial, cultural and morphologic peculiarities, it was thought by careful investigators that the streptococci coming from different diseases could be distinguished by certain characteristic properties. On further study, however, it was found that these properties were not constant, but could be acquired or lost by each of the supposed forms. With the advent of agglutination and immunization tests for the detection and differentiation of bacterial species, it was hoped that if different forms of pathogenic streptococci existed they might be separated by these means.

From reports published by various investigators, we were led to believe that our hopes had been realized. By the application of these methods of study, Fritz Meyer claimed to have differentiated a variety of streptococcus which was characteristic for acute articular rheumatism, and which was the actual cause of this disease. He concluded that by agglutination phenomena the human streptococci can be separated into absolute varieties. For many years it has been known that streptococci are frequently associated with many of the complications of scarlet fever. Baginsky and Sommerfeld found them in the heart's blood and bone-marrow in almost every fatal case, and they appeared to be almost ready to assign them to a causal rôle in this disease. Moreover, Moser now applied agglutination tests to the streptococci cultivated from cases of scarlatina, and concluded that the scarlatinal streptococci were undoubtedly different from those found in other human diseases, such as erysipelas, sepsis, phlegmon, etc. Both Moser and Baginsky claimed to obtain favorable results in cases of scarlatina by the injection of antistreptococcic sera. The serum employed by Moser was obtained from horses which had been injected with cultures of streptococci obtained from cases of scarlatina and without previous passage through animals. Baginsky's serum was prepared by Aronson by the injection of horses with streptococci which had been rendered very virulent by manifold passage through mice. Each author claims special virtue for his own serum. Just as we were in high hopes that at last there was something tangible in our means of separating varieties of streptococci and in combating their effects in human disease, further studies have apparently shown that our expectations were without foundation. The statement of Baginsky that streptococci are constantly present in the blood in cases of scarlatina has been found to be untrue, except in cases terminating fatally after the third day of the disease. In a series of 100 cases in which a bacteriologic examination of the blood was made during life, Hektoen[1] found streptococci in only 12. Deneke examined the blood bacteriologically in a long series of fatal cases of scarlatina. In cases dying during the first 3 days of the disease, he found streptococci only once, but in cases which terminated fatally after the fifth day, streptococci were always present. He holds the idea that streptococci have any essential causal relation with scarlatina to be untenable. Rumpel has used Aronson's serum in 6 severe cases without a recovery, and Deneke has used it in 6 cases without any convincing benefit.

Aronson[2] has recently published some extensive observations on these matters. He has immunized a large number of horses with individual streptococci from various human diseases, the bacteria not having been previously passed through animals, and he has tested the agglutinating and protective properties of the sera from these horses on a great variety of streptococci. He concludes that it is impossible to determine the origin of any streptococcus culture by microscopic examination, by cultural methods, or by agglutination and immunization methods. He is unable to consider the streptococcus as the cause of so typical and characteristic a disease as scarlatina, but admits that it is the cause of most of the severe complications. He states that there is no specific scarlatinal serum, but urges the use of his antistreptococcic serum to combat complications. These observations appear to upset all our ideas as to streptococci which are characteristic of scarlatina and rheumatism. They also show that Aronson's serum which has been used by Baginsky is not to be considered as a specific scarlatinal serum as has been supposed to be the case by many. We are left with only a specific treatment for streptococcus infections in general, which must be subjected to further trial by impartial observers before it can be placed in its final place among our means for combating disease. Our experience in this connection is similar to that in many others. Certain bacteria have often been described as causes of diseases on insufficient data, and without accurate and discriminating observations. Control observations have too often been omitted, and can not be too strongly insisted on in all scientific investi-

1. THE JOURNAL A. M. A., March 14, 1903, 685.
2. Deut. Med. Woch., 1903, No. xxv, 439.

gations. The cautions we urged in our recent editorial[3] regarding extraordinary precaution in the whole technic of the agglutination test are especially apt here. Streptococci have been most elusive in escaping all efforts to obtain accurate knowledge as to their mode of action and to learn any means of overcoming their effects. Present failures must serve to stimulate further study with confidence that in time the difficulties which have so far been unsurmountable will be overcome.

PRIVATE PRACTICE AND HOSPITAL PRACTICE.

If one looks about him and considers the changes which are taking place in medical education, it is easy to see that there is a growing sentiment in favor of the extension of the plan of employing as teachers in medical colleges men who are not engaged in private practice. In the better medical schools the chairs of anatomy, physiology and pathology are already filled with men who devote their whole time to teaching and investigation. We understand that one of the Eastern universities has recently appointed a physician to the chair of internal medicine on the condition that he cease to do private practice and devote himself entirely to the work of the hospital and school. A leading university in the Middle West has advocated strongly the employment of two kinds of professors on its clinical staff, first, professors who give all of their time and energies to the university hospital and medical school, and, second, professors who give a part of their time to the hospital and medical school and the rest of it to private practice.

The advantages of having both kinds of professors in the clinical faculty are sufficiently obvious. Experience in the fundamental branches has shown clearly the advantage to the medical college of having men who, unworried by the cares of private practice and unfatigued by the labor the latter entails, have plenty of time to teach their subjects adequately to medical students and beside to pursue original investigations which contribute to the advancement of science in their particular fields. There can be no question that internal medicine, surgery and obstetrics will be better taught than they are now and that more rapid advances in diagnosis, prognosis, pathogenesis and treatment will be made when scientific men are similarly related to the clinical branches in our universities. Such men, paid salaries large enough to permit them to live respectably and maintain their families properly, could divide their time between the wards of the university hospital on the one hand and the hospital laboratories and library on the other, making observations in the former which would lead to the planning and carrying out of experimental work in the latter. The results of the laboratory work in turn would become applicable to improvement in the methods of study and treatment in the wards. The hospitals so used would probably be comparatively small and especially designed for purposes of investigation; only a few diseases need be studied at any one time, as the investigator prefers to confine his experimental researches to a rather small area for purposes of concentration and intensive study rather than to distribute his attention in any given period over too wide a range. Workers in such research hospitals would not wish to be hampered by too much teaching; they would prefer to be influential by the example they set of thoroughness and originality in procedure rather than by precept. They would gather about them the more advanced and more capable students and lead them into the higher walks of clinical study. By publication of the results of their own observations and experiments they would extend their teaching to other cities and to other lands far beyond the group of students in the school which employed them.

Great as would be the power of a few men of original ideas with strong personality in such research hospitals, the medical school would need also the teaching which the private practitioner of the better sort is so well prepared to give. For private practice is very different from hospital practice, at any rate as the latter exists at present. The hospital physician sees chiefly people who are very sick, men and women who are confined to bed with acute or severe chronic disease. Only in the outpatient department of the hospital does he see the minor ailments with which private practice has so largely to deal; further, in that department the cases are those of charity patients whose slight ailments differ largely from those from which the more well-to-do classes suffer, and when they are the same the treatment has to be very different, perforce, for the poor from that employed for those who are able to pay. The private practitioner is appealed to by men and women in active business or social life in the beginnings of disturbances; his patients are very often not incapacitated, but they are not well; they desire to be told how to correct their lives, what to eat, how much exercise to take and the like. While it is true that the physician in private practice when a teacher in a medical school can not show these patients to his pupils any more than the hospital teacher can, still he sees such patients daily and he can tell his students about them and give them at least some inkling of the best way of handling them. The systematic, vigorous, scientific training of the investigator in the research hospital can thus be most profitably supplemented by the intuition, tact and experience of the successful private practitioner.

3. THE JOURNAL A. M. A., Aug. 8, 1903.

COMPULSORY POSTMORTEMS.

Every physician must have experienced the feeling that is expressed in the following from a daily newspaper editorial. It is entitled "Compulsory Postmortems—They Would Weed Out Criminally Ignorant Doctors and Add Vastly to Medical Knowledge":

When a human being dies this should be the first thought in the mind of the lawmaker and of the bereaved relatives: how can this death, which now causes individual sorrow, be made

useful to all human beings? How can it be made a defense of others in future?

Every doctor will tell you that invaluable information is lost because a sentimental feeling forbids making postmortem examinations. The fond relatives can not bear the thought of an operation being performed on the body of one that they loved. It is useless to tell them that the death is mysterious, that an explanation of its cause might save many lives. They think of nothing but the particular individual now dead. Out of sentiment for the one that has gone beyond help they refuse to help others.

The objections to postmortems are mainly sentimental, but to a certain extent they are fostered by religious beliefs. The same mistaken notions which have led an English bishop to declare against cremation induces many people at the present time to consider an examination of pathologic tissues sacrilegious and resist it with all the power they can exert. We believe, with the editorial quoted, that public opinion should be educated in this matter. "Almost everybody," it says, "now submits the corpse of his friend without hesitation to the process of embalming, which is a repulsive and almost utterly useless postmortem operation." The fact that a little knowledge of the conditions might be of utmost value to the living is never considered by the public, and yet it is a curious fact that when insurance companies demand an examination there is little difficulty in securing permission. Such is the power of self-interest as opposed to sentiment and religious objections.

What the editorial says in regard to the weeding out of unfit physicians by exposing their mistakes is in part true, though it would be unfair to say that mistakes are confined to the ignorant and unfit. The best of us make mistakes, and we desire postmortems in order to avoid making mistakes in the future. Therefore, any facts that the postmortem reveals which are contrary to the expressed views of those treating the patient before death should be given wide publicity before the medical profession. To give them to the public, however, would, in some cases, work an injustice. Still it would not be a serious harm and competent honest physicians could easily live down any possible temporary discredit that it might bring them.

The editorial further urges that compulsory autopsies would do away with much of the present antivivisection agitation by rendering vivisection useless. This argument has some force, though autopsies could not altogether fill the place of animal experimentation, and we believe that the same sentiment which opposes vivisection would oppose making postmortems a means of adding to knowledge. In the main, however, the article quoted in part contains so much good sense that we are glad to endorse it. We wish that every dubious diagnosis could be verified or corrected by an autopsy. The information obtained in such a case would be invaluable, especially in our larger centers where competent operators could be obtained. There is no true physician, we believe, but who would welcome such a regulation. Something, however, can be done in the way of public education as to the necessity and uses of the postmortem examination and more perhaps than by actual regulatory enactment.

ANOTHER DANGEROUS USE OF CELLULOID.

A dealer in London was recently arrested for selling so-called amber and gold cigarette holders which were retailed at the price of 6 shillings and produced at the cost of a shilling or less from celluloid and gilt metal. Celluloid is a useful substance, but it has its drawbacks. Its employment as a cigar holder seems to possess about as many drawbacks as any other use that might be suggested; it is not long since we read of an unfortunate Parisian whose celluloid nose blew up. We are afraid that some of these cigar holders will be found a source of danger to their possessors. The old-fashioned trick of loading pipes and cigars with gunpowder is humane in comparison with the possibilities of a practically guncotton cigar holder held in the mouth and ignited from a partially burned cigar or cigarette. We wonder how many "amber" celluloid cigar holders are in use and how soon we shall hear from them.

CAT GRAVEYARDS.

It is reported in the daily press that a society for the prevention of cruelty to animals in a leading Eastern town is promoting the establishment of a cemetery for dogs and cats and is soliciting subscriptions therefor. The city where this society exercises its function is already notable as the only one in the country containing a well-built—and we believe it is also well-endowed—asylum for homeless cats. While we do not object to zoöphily when it does not interfere with more important matters, it does seem to us that there is danger of overdoing this sort of thing. While so large a proportion of our own species suffers from neglect, and needs care in hospitals and asylums and lacks the means of decent burial, to establish hospitals and cemeteries for dogs and cats seems to us a *reductio ad absurdum* of benevolence. All animals should be humanely treated and, when they can not be cared for, should be mercifully killed to prevent suffering or abuse; some even, in memory of lives they have saved, deserve more, but a cemetery for dogs and cats will be pointed out as a curiosity and a proof of human folly rather than an evidence of intelligence or of humanity.

HYPNOTISM AN ANESTHETIC FOR MAJOR OPERATIONS.

The successful amputation of a limb under hypnotism is reported[1] in a patient suffering from necrosis of the bone and severe ulceration of the leg. In a previous operation the patient bore the anesthetic badly and hence wished to be relieved of the necessity of taking another. Hypnotism was used as a last resort. The operator refused to work unless the means for anesthesia were at hand, but fortunately their use was not required. The patient went through the operation successfully, and the temperature at no time was above normal. Recovery was uneventful except for a slight hemorrhage and sloughing of a portion of the flap, which was not accounted for. While we believe that hypnotism as a therapeutic remedy has long passed its heyday, its occasional use will doubtless still be heard from and may be—like other seldom-used but once-in-a-while-effi-

1. The Lancet, London, August 22.

cient remedies—found of value. We must take into account the fact that susceptibility to hypnotism is very variable, and while fifty or sixty years ago large numbers of cases of operations under this method were reported in India, it speedily passed out of use. Few operators, we venture to say, would ever now rely on it. As the *Lancet* says in its comments on the case, it can only be regarded to some extent as a curiosity, though the issue was favorable.

PHYSICIANS' COMMISSIONS ON REFILLED PRESCRIPTIONS.

The Journal has received through a correspondent a copy of a circular letter sent out by a drug manufacturing firm, which we do not care to advertise here by a name, proposing to allow physicians 10 per cent. commission on the refills of prescriptions of the firm's preparations. They argue that the physician is entitled to something on the refilling of his prescriptions, but, under the usual practice, he alone of the trio—manufacturer, retailer and prescriber—does not profit. It is easy to see how the manufacturer hopes to increase his profits if the physician will only co-operate. The professional aspect of the transaction is another thing. No matter how excellent the products of this firm may be, and we know nothing about them, no ethical physician would accept a commission for prescriptions and much less we should say for their unauthorized repetition, as is implied in the circular letter referred to. It is only a bid for more business, with a rather cleverly devised trap for physicians included. If the ethical argument is not sufficient, those who are incapable of fully appreciating its force may also consider the fact that advertising proprietary remedies and encouraging the public into the practice of self-dosing with them, as is suggested by the circular, is a bad practice financially for the physician and physically for the patient.

Medical News.

CALIFORNIA.

In Memory of Dr. Gardner.—In memory of the late Dr. Matthew Gardner, San Francisco, and to show the high respect they bore him, the San Francisco County Medical Society, at its meeting, August 11, passed resolutions.

State Board Election.—The State Board of Medical Examiners has elected the following officers: Dr. Dudley Tait, San Francisco, president; Dr. Lewis A. Perce, Long Beach, vice-president; Dr. Charles L. Tisdale, Alameda, treasurer, and Dr. George G. Gere, San Francisco, secretary.

In the Toils.—"Dr." H. G. Wright, Cloverdale, was fined $100 for practicing medicine without a license in that town.——Ma Too Ting of Stockton, twice tried for practicing medicine without a license and on whose case two juries have disagreed, has been discharged.——"Dr." Myers, an optician of Hanford, found guilty of impersonating an agent of the State Board of Health and sentenced to 100 days in jail and a fine of $100, has been surrendered by his bondsmen, and is in jail in Fresno.

Physicians Injured.—Dr. William D. McDougall, San Jose, was seriously injured in a runaway accident, July 24.——Dr. Malek A. Southworth, San Jose, who was injured July 3, is rapidly recovering.——Dr James H. McLeod, Santa Rosa, was thrown from his buggy, July 7, sustaining a strain of the arm and a severe scalp wound.——Dr. Charles E. Turner, Vallejo, was thrown out of his buggy in a runaway accident, August 7, and fell on his back, causing concussion of the spine.

Personal.—Dr. Thaddeus S. Up de Graff, Pasadena, has returned from a trip round the world.——Dr. Dwight H. Trowbridge has been made a member of the Fresno Board of Health, vice Dr. George H. Aiken, resigned.——Dr. William F. Snow, Stanford University, has been appointed deputy health officer of Santa Clara County during the absence of Dr. Ray L. Wilbur in Europe.——Dr. W. R. T. McLain, Los Angeles, sailed for Europe, August 19.——Dr. and Mrs. Norman H. Morrison have returned to Los Angeles, after a trip to Hawaii.——Dr. Silas Johnson, Los Angeles, has returned to his work as a medical missionary on the west coast of Africa.

GEORGIA.

Georgia to Kansas.—Dr. Middleton L. Perry, Milledgeville, has been appointed superintendent of the new state hospital for epileptics at Parsons, Kan.

Hospital Staff Elects Officers.—The staff of Griffin Hospital has elected Dr. Robert H. Taylor, chairman; Dr. Thomas J. Collier, vice-chairman, and Dr. Joseph M. Thomas, secretary and treasurer.

State Board of Health Bill a Law.—The governor signed the State Board of Health bill, August 17. The bill provides for a board of eleven members, one from each congressional district, with a secretary whose office shall be in the capitol. The secretary is to receive a salary of $2,000 a year. The board elects its own president. The members receive no salaries, but are paid $5 a day when in attendance on meetings.

Appoints State Board of Health.—Governor Terrell has appointed the following members of the State Board of Health: Drs. F. M. Ridley, La Grange; Willis F. Westmoreland, Atlanta; Robert M. Harbin, Rome; Giles Hathcock, Belton; Charles Hickes, Dublin; William W. Owens, Savannah; Augustus P. Taylor, Thomasville; Millard S. Brown, Fort Valley; Howard J. Williams, Macon; Samuel C. Benedict, Athens, and James B. Morgan, Augusta.

ILLINOIS.

Personal.—Dr. Thomas W. Curry, Streator, has returned after an absence of five months in Europe.

Hospital Opened.—The new St. Mary's Hospital, Rockford, remodeled and newly equipped, is now open.

New Hospital for Evanston.—A new hospital, to be called the Grove House for Convalescents, is to be established in North Evanston. The building will cost $5,500 and will be ready in the early spring.

Smallpox Hospital Out of Commission.—After having maintained a smallpox hospital for two months, the authorities of Libertyville, Lake County, have decided that the town is free from smallpox, and have closed the hospital.

Magnetic Healers Held.—In the case of "Drs." Parker and Hall, the alleged magnetic healers, Judge Green, sitting at Pekin, has held that they are not entitled to their release, thereby intimating that the state has a case against them of sufficient strength to warrant their being held to await the action of the grand jury.

Chicago.

Assaulted While Saving Life.—While working to save the life of a woman who had swallowed carbolic acid Dr. William H. Crowley was attacked and beaten by a man. It was later alleged that the man was concerned in the woman's reason for attempted suicide.

Smallpox More Fatal.—The Department of Health reports that smallpox is of a more serious type this year than last. In 1902 there were 338 cases with only 5 deaths—a mortality rate of less than 1.5 per cent. Thus far this year there have been 346 cases and 45 deaths—a mortality rate of 13 per cent.

Medical Colleges Taxed.—The board of review has decided that medical colleges operated for profit shall be taxed on their equipments. Rush Medical College was taken under advisement; Hahnemann Medical College was not taxed; Chicago Homeopathic Hospital was taxed on $4,000, and the American College of Medicine and Surgery, Bennett Medical College and Jenner Medical College on $2,000 each.

Dearborn Medical College.—A new evening medical college held its opening exercises, September 1. Judge R. S. Tuthill delivered the opening address. About 175 students make up the initial enrollment. Dr. L. Blake Baldwin is president of the college and Dr. James L. Wells, secretary. The college building is that formerly occupied by Bennett Medical College, and later by the Chicago College of Pharmacy. A clinical building is now being erected.

Personal.—Dr., Mrs. and Miss Hotz have returned from a visit to Yellowstone Park.——Dr. Charles H. Parkes has returned after a year in Europe.——Dr. Joseph P. Smyth, has been elected high medical examiner of the Independent Order of Foresters.——Dr. and Mrs. Arthur D. Bevan are spending August in the White Mountains.——Dr., Mrs. and Miss Chew will return from Europe early next month.——Dr. and Mrs. Philip S. Doane have returned from Harbor Point, Mich.——Dr. Henry H. Everett has returned from a ten weeks' trip through New Mexico.——Dr. J. F. Bichn has been appointed assistant city bacteriologist, vice Dr. L. A. Kiernulff, resigned.

The Typhoid Situation.—The Department of Health reports that physicians are asking for far more laboratory examinations of suspected cases of typhoid fever than formerly. The disease is not on the increase to any extent. An investigation of twenty-two recent cases in the "ghetto" of the Nineteenth Ward was made by Medical Inspector Dr. Palmer Findlay, who reports that in sixteen families, where positive information could be obtained, untreated (unboiled) hydrant water was habitually used. No connection could be established between the cases and the milk supply. The sanitary conditions—including plumbing, vaults and closets—were "O. K.," "clean" or "fair" in fourteen cases and "bad," "full" or "in a filthy condition" in eight cases. The dense ignorance and unclean European habits of the denizens were the only obvious causes of the excess of the disease in this district.

INDIANA.

Gift to Hospital.—In accordance with the wish of her husband, the late Dr. William C. Eichelberger of Terre Haute, Mrs. Eichelberger has given all his surgical instruments and medical books, safe, office fixtures and furniture to the Union Hospital.

Dr. Brayton's Illness.—Dr. Alembert W. Brayton, Indianapolis, editor of the *Indiana Medical Journal*, who has been ill for several weeks, was operated on for abdominal abscess, August 25. The operation was successful, and Dr. Brayton is expected to make a rapid recovery.

Personal.—Dr. George D. Kahlo has succeeded Dr. Allison Maxwell as dean of the Central College of Physicians and Surgeons, Indianapolis. Dr. Maxwell will retain the chair of clinical medicine.——Dr. John A. Martin, La Fayette, surgeon at the Soldiers' Home, has resigned.

Deferred Union of Medical Colleges.—It is said that no further progress has been made in the proposed amalgamation of the Medical College of Indiana and Central College of Physicians and Surgeons. No definite conclusion has been reached, and it is said that each college will hold a separate session this year. Each college has issued its catalogue for the coming session.

In Trouble.—Mrs. Effie Watson, Martinsville, has been fined $25 for practicing medicine without a license. She is alleged to have practiced "cycopathy."——"Dr." Frank J. Sazofsky, also of Martinsville, has been fined $25 for practicing medicine without a license.——"Dr." James Charles, a manufacturer of electrical appliances of Richmond, has been indicted by the grand jury for practicing without a license.——An itinerant of Van Wert, Ohio, was recently arrested in Shelbyville for practicing without a license and selling medicine on the street, and was released on giving bond for his reappearance.

Disease and Death in July.—The regular monthly bulletin of the State Board of Health says:

The health for July throughout the state is slightly better than in the preceding month, and was also better as compared with the corresponding month of last year. Diseases of the digestive tract were most prevalent. There was a great decrease in smallpox, as compared with the preceding month and with the corresponding month of last year. The order of prevalence of diseases was as follows: Diarrhea, cholera morbus, rheumatism, cholera infantum, typhoid fever, dysentery, tonsillitis, intermittent fever, bronchitis, scarlet fever, inflammation of bowels, measles, whooping cough, pleuritis, pneumonia, diphtheria and croup, erysipelas, influenza, puerperal fever, cerebrospinal meningitis.

There were 104 cases of smallpox with 4 deaths reported in 21 counties. In the corresponding month of last year there were 502 cases reported, with 15 deaths in 46 counties.

An interesting fact in conjunction with deaths by violence appears in the report from Evansville, where 10 persons were killed by mob violence. There were, in all, 13 murders during the month. The suicides numbered 30; males, 22; females, 8. The accidental deaths numbered 159. The deaths from tuberculosis numbered 360; males, 147, and females, 213. The married persons between the ages of 18 and 40 who died of the disease, leaving orphans, was 98. One hundred and fifty-two mothers died and 44 fathers, leaving 196 children under the age of 12. The total number of deaths from all causes for the month was 2,765, an annual rate of 12.9 per 1,000. The rate in the corresponding month last year was 13.6 per 1,000. By certain ages the deaths were: Under 1 year of age, 541, or 20.7 per cent. of the total; from 1 to 5 years, 214; 5 to 10 years, 55; 10 to 15 years, 75; 65 and over, 679, 26 per cent. of the total. By comparison with the same month last year we find the deaths of children under 1 year of age were greater. The percentage for June, 1902, was 19.6 per cent. of the total deaths. Some important causes of deaths were as follows: Tuberculosis, 362; typhoid fever, 63; diphtheria, 13; scarlet fever, 12; measles, 6; whooping cough, 14; pneumonia, 77; diarrheal diseases, 313; influenza, 11; cancer, 108; violence, 102; smallpox, 4.

IOWA.

Eye Doctor Bound Over.—J. Edmund Wilson, an "eye doctor," who was arrested at Clarion, August 14, for practicing medicine without a license, has been bound over to the grand jury under bonds of $300.

Dr. La Force Improving.—Dr. D. A. La Force, one of the pioneer physicians of Ottumwa, was taken seriously ill while attending the G. A. R. reunion in San Francisco, and was in so dangerous condition that his son, Dr. William B. La Force, was telegraphed for. He is now reported as greatly improved, and is considered out of danger.

Personal.—Dr. Lewis Schooler, professor of surgery and clinical surgery in Drake University Medical Department, Des Moines, has resigned.——Dr. Earl Rice, Roland, has been seriously ill with blood poisoning following an operation wound.——Dr. Montrose Conley, Boone, has been appointed an interne in the Cook County (Ill.) Hospital for the Insane, Dunning.——Dr. James G. McAlvin, Grundy Center, will go abroad for a year's study.——Dr. Lawrence W. Littig, Iowa City, has been appointed lecturer on nervous diseases in the University of Iowa College of Medicine.

Cherokee Hospital Report.—The State Hospital for the Insane at Cherokee, opened August 15, 1902, had at the end of a year 619 inmates, 347 men and 272 women. The proportion of recoveries was 26 per cent., and of mortality 6.5 per cent. Of those who died, 24 per cent. were more than 70 years old. Since the opening of the inebriate department, Oct. 10, 1902, 151 males and 3 females have been admitted. Of these 28 escaped, and with 61 paroles, one death and transfers only 35 remained at the time of the report. Of the 154 patients, 118 used whiskey; 18, alcohol; 13, beer, and the remainder cocain or morphin.

KENTUCKY.

Dysentery Epidemic.—Dysentery is reported as epidemic in the Polkville neighborhood.

Verdict Against Physician.—In the case of G. B. Bailey against Dr. W. M. Lottridge, Newport, wherein $10,000 damages was claimed for alleged malpractice in the care of a broken leg, a jury awarded the plaintiff $2,000.

Personal.—Dr. Joseph M. Mathews, Louisville, has resigned from the faculty of the Hospital College of Medicine, and will devote himself to private practice.——He has been succeeded by Dr. George A. Hendon, formerly assistant to the chair of surgery.

House-to-House Inspection.—Health inspectors under the direction of Dr. Maverell K. Allen, health officer of Louisville, are making an inspection of the sanitary condition of every house in the city. The reports of the inspectors will be filed with the health officer, and will be kept up to date.

College Improvements.—The trustees of Central University have sanctioned the expenditure of about $15,000 for remodeling the building of the Hospital College of Medicine, Louisville. Two new laboratories and new amphitheaters and section rooms are to be built, and the grounds of the school are to be beautified.

Where They Spent Their Vacations.—Dr. Joseph M. Mathews, at Harbor Springs, Mich.; Dr. Lewis S. McMurtry, in Canada; Dr. Thomas Hunt Stucky, at Atlantic City; Dr. Henry Enos Tuley, at Reserve, Wis., fishing; Dr. John G. Cecil, on the Pacific Coast and Yellowstone Park; Dr. Curran Pope, at Michigan resorts; Dr. Orville Kennedy, at Grayson Springs, Ky.; Dr. J. Rowan Morrison, at White Sulphur Springs, Va.; Dr. James S. Chenoweth, in Maine, and Dr. J. B. Marvin, at Cape Cod, Mass.

LOUISIANA.

Low Mortality.—The mortality in New Orleans for the first week in August was at the annual rate of 14.66 per 1,000 for whites and 21.98 for negroes, or a total rate of 16.60.

Personal.—Dr. Jefferson D. Bloom, house surgeon of Charity Hospital, New Orleans, for more than seven years, has resigned.——Dr. C. Jeff Miller has been elected to the chair of surgery in the New Orleans Polyclinic.

Bad Milk.—Numerous complaints have been made of the milk supply of New Orleans. Several cases of poisoning from tyrotoxicon and from adulterated milk have been reported. The City Board of Health has preferred charges against a number of milk dealers and proposes to adopt a vigorous campaign for a pure milk supply.

Sewage and Water System for New Orleans.—The work of constructing the vast system of sewage, water and drainage, which is to place New Orleans abreast of the best sanitated cities of the world, and which is to cost, roughly, $18,000,000, is already well in hand. The great undertaking is to be finally completed within the next five years. The movement which culminated in this great work followed the epidemic of fever in 1898. The system is to be fully described and illustrated in THE JOURNAL in a few weeks.

Charity Hospital Staff.—At a recent meeting of the board of administrators of the Charity Hospital, Dr. J M. Batchelor was elected house surgeon, to succeed Dr. J. D. Bloom, who resigned after a service of sixteen years. Dr. J. A. Danna was promoted from second to first assistant house surgeon, and Dr. S. W. Stafford was elected second assistant. It was determined by the board that in the future the second assistant should be selected by competitive examination. The term of house surgeon was by resolution limited to six years. The board also adopted resolutions denying the truth of the rumor as to its policy in regard to the Sisters of Charity. The latter are not to be disturbed in any way.

Mitigate Quarantine Regulations.—At a conference of the state quarantine officials of Louisiana, Alabama and Texas, held recently in New Orleans an agreement was reached, which will greatly mitigate the quarantine regulations controlling travel and commerce from Cuba to ports on the Gulf of Mexico. The following was the resolution adopted:

Resolved, That on and after August 6 all uninfected vessels from clean Cuban ports be admitted to free pratique after thorough inspection at the quarantine station, including taking the temperatures of all on board, disinfection of soiled clothing and containers and other suspected articles, either by steam heat or formaldehyd, and that passengers from Cuban ports be permitted entry without further restrictions, provided that each passenger furnishes a certificate from the chief medical officer of the Cuban port of departure stating that said passenger has resided not less than five days in Cuba prior to sailing from that island. Agents of steamship lines in Havana, on delivering their tickets to passengers, shall instruct them to place all their soiled clothes and linen in a separate bag, trunk or box in order to simplify quarantine regulations at the home port.

Should any soiled clothes and linen be found among unsoiled clothes and linen the whole package shall be disinfected.

The vessel may be disinfected at the direction of the quarantine authorities.

MISSOURI.

Due to Floods.—The death rate of Kansas City for July was the highest in the history of the city, 324 deaths having been reported. Of these, 24 were caused by typhoid fever, due to unsanitary conditions following the recent flood and the drinking of impure water.

Bacilli in Street-Car Sweepings.—The St. Louis Transit Company has begun a scientific investigation of the sweepings from street cars to discover a means of keeping the cars sanitarily clean. Bacteriologist Stolpher has submitted a report showing that as the result of his examinations of car sweepings for a week, all the cars contained tetanus and tuberculosis bacilli.

Professor Acknowledges Fraud.—Dr. Frank O. Reynolds, professor of bacteriology, microscopy and hematology in Ensworth Medical College, St. Joseph, and curator of the college museum, on account of his acknowledged connection with "the New York Hospital Company of St. Joseph," a fraudulent scheme, was requested to tender his resignation, promptly did so, and it was as promptly accepted.

To Prosecute Unlicensed Physicians.—The chief of police of St. Louis, on request of the health commissioner, has instructed each patrolman to get the names and addresses of all physicians on his beat. When the returns are complete the lists are to be sent to the health commissioner, who will sort out those known not to be reputable. Those who are found to be practicing without having complied with the state laws will be prosecuted.

NEW YORK.

New Hospitals at Albany.—Two new hospitals will be built at Albany, one a smallpox hospital, the other a pavilion for the reception and care of patients suffering from contagious disease.

For Dr. Richardson's Place.—Dr. William A. White, first assistant of the Binghamton State Hospital, has received from the Secretary of the Interior the appointment as superintendent for the Government Hospital for the Insane at Washington, D. C., vice Dr. Alonzo B. Richardson, deceased.

Buffalo Personals.—Drs. John H. Mesmer, E. J. Meyer and Henry Buswell have gone to Northern Canada on a fishing trip. ——Dr. James W. Putnam has returned from Magnolia.——Dr. Frank W. McGuire was appointed gynecologist to the Buffalo German Hospital, vice Dr. Herman E. Hayd, appointed surgeon. ——Drs. Irving M. Snow and Lillian Craig Randall are in Europe.

To Examine Condemned Criminals.—Governor Odell has appointed Dr. Eugene H. Howard and Dr. Arthur W. Hurd medical superintendents of the Rochester and Buffalo State hospitals, respectively, to examine the mental condition of Patrick Conklin, awaiting execution at Sing Sing. Dr. Henry E. Allison of Matteawan and Dr. Morris G. Ashley of Middletown were also appointed to examine Clarence Equar, awaiting execution at Auburn state prison.

Radium and Blindness.—Dr. Almon Jenkins and Mr. W. J. Hammer, an electrical engineer, are engaged in some interesting experiments with radium on a blind girl. That the optic nerve of this child is practically dead would seem to be shown by the fact that it is stated that the child saw nothing when magnesium ribbon was burned before her eyes, yet it is claimed that under the conjoined action of the *x*-ray and radium the child declared that she saw light. While there is no likelihood that these experiments have any practical bearing, they are of interest in connection with a study of the marvelous properties of the new substance radium.

Pure Water for Ithaca.—The turbine pumps which deliver water to the new Fulton plant of the Ithaca Water Company were set in motion, and the citizens of Ithaca and the students of Cornell are assured of an abundant supply of pure water. Although tests had been in progress in the plant several days, no announcement was made until yesterday that it was ready for operation. Six months ago Cornell loaned to the Ithaca Water Company $150,000 for the building of the purification plant, and work has been continuous since. The water, as soon as delivered to the receiving wells, is charged with a solution of sulphate of alumina, which forms a white, flaky precipitate. The water is then passed into coagulating basins, where 70 per cent. of its impurities settle. It is then passed through six filters of a capacity of 3,000,000 gallons daily.

OHIO.

Hospital Gets Library.—Dr. James C. Culbertson, Cincinnati, editor of the *Lancet-Clinic* and member of the board of education, has given his medical library of over four hundred bound volumes to the City Hospital medical library.

Personal.—Dr. Peter Donnelly, Toledo, has been appointed a member of the local board of health.——Dr. Guy H. Williams has been appointed assistant physician at the Columbus State Hospital, vice Dr. Ralph Holmes, who has accepted a similar position at the Ohio Hospital for Epileptics, Gallipolis.——Dr. and Mrs. Charles J. Shepard, Columbus, sail for Europe on the *Molkte*, October 1.

Almost Free from Smallpox.—Dr. C. O. Probst, secretary of the State Board of Health, announced, August 20, that Ohio was practically free of smallpox. There was then only one place in Ohio that had anything bordering on an epidemic, there being 18 cases at Massillon. Cleveland has discharged the last patient from the pest house and is free from the pest for the first time in many months.

New Hospital in Cleveland.—A new hospital has been opened in Cleveland under the name of "The Mt. Sinai Hospital of Cleveland, Ohio," by philanthropic Jewish citizens. It is strictly non-sectarian. It is well equipped to accommodate thirty-five patients, with ward and private beds. The staff is made up as follows: Surgeons—Drs. George W. Crile, Carl A. Hamann and Frank E. Bunts; gynecologists—Drs. Marcus Rosenwasser, W. Lincoln and John J. Thomas; orthopedic surgeon—Dr. Walter G. Stern; pediatrists—Drs. Nathan Weidenthal, and McMichael; eye—Dr. William E. Shackelton; nose and throat—Dr. Henry B. Stotter; skin—Dr. Samuel Rigelhaupt; nervous diseases—Drs. Moritz Lowenthal and Isidor Belkowsky; internal medicine—Drs. Arnold Peskind, Friedman. Emanuel Rosenberg, Louis Robecheck, David B. Steuer, Alfred S. Maschke, Daniel Heimlich, Kaplin, Isador J. Propper, Maurice Budwig and Myron Metzenbaum. Dr. Bunts is president and Dr. Stern secretary.

PENNSYLVANIA.

Typhoid in Schuylkill County.—An epidemic of typhoid fever is reported in Schuylkill county, there being many cases at Ashland, Pine Grove and Pottsville.

Dogs Quarantined.—The State Live Stock Sanitary Board, because of evidence of rabies existing among the dogs of Columbia County, has ordered all quarantined for a period of 90 days.

Dairyman Fined.—A dairyman at Mahanoy City, pleading guilty of using formaldehyd in milk, was recently fined $100 and costs amounting to $19.64; and a Locust Valley farmer for using ice in his milk was fined $62.50, including costs.

Philadelphia.

Phipps Institute.—The educational work of the Phipps Institute was opened on August 25 by Dr. Ward Brunton, one of the physicians of the institution, who gave to a lay audience a lecture on "The Cause and Prevention of Tuberculosis."

Public Playground.—The thirty-five playgrounds, mostly school yards, which have been open in different sections of the city during the summer under the auspices of the Board of Education, closed August 28. The total attendance for July was 158,646. This seems a practical contribution to the health of the children of the poor.

The New Filtering System.—Chief Hill of the filtration bureau has published a series of results of recently completed sand filters of the new system being installed. The results are the best ever attained by such methods. On August 8 the Schuylkill river water showed 42,000 bacteria per c.c.; one of the Lower Roxborough filters reduced the number to 12, while the poorest showing was 68 to the cubic centimeter. This filter system will be described in THE JOURNAL in the near future.

Reports of Contagious Diseases.—The Department of Public Health and Charities, to facilitate the report of contagious diseases, has sent to each physician postal cards properly printed for such reports. A circular letter accompanies the cards asking special aid of the profession in stamping out smallpox. To this end a request is made that all cases of chicken-pox be reported, and that especial influence be exerted toward having all persons vaccinated who are not so protected. The office of the bureau of health will hereafter be open night and day and never closed. In order to impress the public with the necessity of vaccination, the bureau is distributing a circular, citing a number of concrete examples of the manner in which vaccination protects. Among other examples cited, it is pointed out that of the 2,600 smallpox patients admitted to the Municipal Hospital within the last two years there was not one person who had been recently successfully vaccinated.

GENERAL.

Leprosy Scare in Porto Rico.—The people of this island are much alarmed over the discovery that fowls, produce and other articles were freely brought from the leper settlement to San Juan. The regulations of the settlement were said to be very lax.

The Reed Memorial Fund.—The committees appointed for the purpose by the American Medical Association, the American Association for the Advancement of Science, and the Congress of American Physicians and Surgeons met, August 15, in Bar Harbor, together with friends of the late Major Reed, M.D., U. S. A. Representative men were present from different parts of the country, and letters were received from various members of committees already appointed to promote the collection of a memorial fund in grateful commemoration of Dr. Reed's services in connection with yellow fever. Important suggestions were presented from President Eliot, Dr. W. W. Keen, Prof. J. W. Mallet and others. Dr. Daniel C. Gilman, chairman of a committee appointed by the American Association for the Advancement of Science, presided, and Dr. Stuart Paton acted as secretary. Among those who took part in the conference were Dr. W. H. Welch of Baltimore, Dr. Janeway of New York, Dr. Abbott of Philadelphia, Dr. Herter of New York, Dr. Barker of Chicago, Dr. Putnam of Buffalo, Dr. Fremont Smith of Bar Harbor and Dr. Sajous of Philadelphia, and beside these medical gentlemen, Bishop Lawrence of Massachusetts and Messrs. Morris K. Jesup, president of the New York Chamber of Commerce, John S. Kennedy, president of the Presbyterian Hospital of New York and William J. Schiffelin of New York. The following conclusions were reached: That an effort should be made to raise a memorial fund of $25,000 or more, the income to be given to the widow and daughter of Dr. Reed, and after their decease the principal to be appropriated either to the promotion of researches in Dr. Reed's special field, or to the erection of a memorial in his honor at Washington. Arrangements were made for the publication of circulars explaining this movement, and asking co-operation not only from the medical profession, but from all liberally disposed individuals who appreciate the value of Dr. Reed's services to mankind.

FOREIGN.

The Next International Dermatological Congress.—The fifth congress will meet in Berlin, Germany, September 13 to 17, 1904. The following subjects have been selected by the officers of the congress for discussion: "The Syphilitic Affections of the Circulatory Apparatus," "The Diseases of the Skin in Anomalies of Metabolism," and "Epitheliomas and Their Treatment." Dr. James Nevins Hyde, 100 State St., Chicago, has been appointed secretary for America.

The First German Total Abstinence Congress was opened, August 8, with simultaneous subsidiary societies of teachers, women, clergymen, etc. The Berlin correspondent of the *Muenchener Med. Woch.* notes that there are no special branches of total abstaining physicians, and rather offers his congratulations that the number of abstainers among German students is something hardly more than one-tenth of 1 per cent. Nevertheless he states that at the same time with the Total Abstinence Congress a general meeting of the world-wide Good Templars Order was held, which in Germany at the present time has some 625 lodges with almost 20,000 members and has in late years added nearly 4,000 to its membership.

LONDON LETTER.

Dinner to Mr. Jonathan Hutchison.

A complimentary dinner has been given to Mr. Jonathan Hutchinson on his seventy-fifth birthday by the members of the profession. Sir H. G. Howse, late president of the Royal College of Surgeons, presided, and covers were laid for 154 guests. In proposing the health of Mr. Hutchinson the chairman said that he was a professional of 53 years' standing, and the astonishing virility and vitality he had shown within the last two or three years was not an unfitting part of his career. Who among them, he asked, would, at the age of 73, undertake a long journey to South Africa in search of facts which might damn or support an hypothesis, and who would subsequently undertake a similar journey to India? Though the occasion was Mr. Hutchinson's 75h birthday, they still hoped to see more of his work, for he was still capable of studying facts which would be useful to the profession in the future. Sir Joseph Fayrer, who also spoke to the toast, remarked that he had always read Mr. Hutchinson's books with profit, and had learned to look on him with profound respect. What had struck him most was the energy with which Mr. Hutchinson had pursued his studies up to his 75th year with fidelity of conscience and with the true scientific spirit, always striving to ascertain what was right simply for the sake of right. Mr. Hutchinson, in response, referred to the healthy feeling and pride he felt in knowing that he had gained the esteem of so many influential friends. Such recognition helped him on in his work. This, of course, was not the highest motive, but though one should be actuated by high motives it was no harm to have them reinforced by lower ones. He thanked Sir Joseph Fayrer for mentioning fidelity to conscience. This he had been brought up in from his youth by the Society of Quakers, among whom the one dogma was conscience. Turning to the question of leprosy he related how, when visiting Robben Island (near Cape Town) he saw 500 persons confined for life because the medical profession were too indolent to pay proper attention to facts. Leprosy was not contagious, and yet on Robben Island were confined the children of white parents condemned to association with Kaffirs and Hottentots. Therein lay a motive for work in what remained to him of life—to render the profession alive to its duty with regard to leprosy. Poetry had always inspired him with motives for dry scientific work. He always tried to act up to the motto of the German poet, "Keep true to the dream of your youth." He also quoted with approval the view of a Swedish writer as to the distinction between fame and immortality. Fame consisted merely in having one's name known and diffused about, but immortality consisted in having one's work taken up and carried on by one's fellows, though one's name might be forgotten.

The Professorship of Surgery at the University of Cambridge.

Mr. Howard Marsh, surgeon to St. Bartholomew's Hospital, has been appointed professor of surgery in the University of Cambridge in succession to the late Sir G. M. H. Humphry, since whose death seven years ago the professorship has been suspended.

Correspondence.

Notes from Paris and Berck.

Paris, August, 1903.

To the Editor:—Berck-sur-mer, a health resort on the Normandie coast, is best known outside of France through the work of Dr. L. Calot in the treatment of tuberculous and deformed children. On Dr. Calot's invitation the writer drove directly to his private hospital, a fine large building on the elevated drive facing the broad, sandy beach, where a fleet of some fifty dark fishing smacks was stranded. The hospital is managed by sisters of charity, and is very complete in all its appointments; the rooms are large, and most of them connect with balconies, where the patient can pass his time in the open air if unable to go to the beach. Most of the children, however, play on the beach; many who are unable to walk being carried out and placed on mattresses on carts. While much less use seems to be made of mechanical supports or of operative treatment than is the rule with us, the chubby appearance and ruddy faces of the children testified to the beneficial effects of this mode of life.

Dr. Calot begins his daily clinic at 4 p. m. in a spacious and well-appointed building connected with the hospital. There is a series of roomy offices and operating rooms and waiting rooms, affording every facility and convenience. A feature of the work is the injection treatment of tuberculous joints, glands, abscesses and sinuses. Cold abscesses are never opened; joints and glands are never excised, but are injected with iodoform-guaiac and camphorated naphthol every three or four days. The hips and spine, however, are not well suited to the injection treatment. Inflamed joints are immobilized in plaster splints, in which a window is cut for access to the joint, and if the case is acute the patient is kept recumbent. By these means combined with the sea air and sunshine many cases are cured without suppuration. Dr. Calot's method of forcible correction of the kyphotic spine was at one time very largely practiced, but is now used in a much milder form, even by its author. A corrective jacket was applied during suspension in the ordinary way and without anesthesia; the jacket, however, reached over the shoulders and included the neck, chin and occiput. While the plaster was hardening manual pressure was made over the kyphos. Afterward a large fenestra was cut in front and behind, the posterior opening being stuffed tightly with a large quantity of cotton, which was bandaged on. Dr. Calot believes that he is able in this way to exert a great deal of pressure on the kyphos without danger of a pressure sore. Dr. Calot has modified the technic of the replacement of congenital hip dislocation, by adding a strong inward rotation after the hip is reduced, either at the same sitting or a few days later, by which means he believes the head is forced more strongly and exactly into the acetabulum. His cases are all *x*-rayed in the operating room at the time of operation, and as in Liverpool and Paris. The finished plate is shown "while you wait." A long plaster spica is applied with the knee flexed, and the patient does not walk. In one case examined the patient was walking without support after five months' treatment, and by palpation, measurement and *x*-ray the reduction seemed perfect. As a rule treatment is over in five or six months. The writer left much impressed with Dr. Calot's kindness, earnestness and skill, and with the value of the open air and beach treatment of bone and joint tuberculosis.

In Paris the writer was so fortunate as to meet both Professor Kirmisson and Dr. Redard, both well known in America by their work and writings. Dr. Redard, who has just been distinguished by the red button of the officer of the legion of honor, devotes two mornings a week to the orthopedic service at the Furtado-Heine dispensary, a large, modern building in the Rue Delbet. Through Dr. Redard's extreme kindness, the writer was present at a private operation for manual replacement of a congenitally-dislocated hip in a rather thin girl of twelve. It was surprising to observe that the movements were made with great deliberation, with pauses between the different steps, and with no manipulation of the adductors, which readily yielded to the steady stretching, and in less than twenty minutes the hip was in place, without violence, bruising or injury. The ease and skill with which this was done were a revelation. It was noticed that during reposition the thigh was strongly flexed. The short spica is left off in five or six months.

Dr. Kirmisson, who occupies the chair of surgery of children in the University of Paris, spends several hours every morning at the fine new Hôpital Trousseau. He studies his cases very carefully, and impresses one by his good sense, moderation, and excellent judgment. He is opposed, as a rule, to the excision of joints in children, treats tuberculous abscesses and sinuses by the injection of iodoform-ether, and when there is acute disease keeps the patient in bed. Professor Kirmisson is not enthusiastic about tenoplasty in infantile paralysis, but thinks highly of arthrodesis. He spoke of the lack of careful reports of final results. In the manual replacement of congenital hip luxation, Professor Kirmisson lays great stress on reduction over the inferior border of the acetabulum, which he believes is much easier. It is effected by extreme flexion followed by external rotation, after the hip has been brought down and the resistance of the adductors overcome in the usual way.

After the work at the Trousseau, Professor Kirmisson goes each Wednesday to his ambulant clinic at the Hôtel Dieu, as he says, to observe the results of other methods of treatment. Curiously, on the day when the writer was present, three adults whose hips had been excised in childhood presented themselves. Everyone was horribly crippled, with a short, weak, deformed and nearly useless leg, and furnished a strong argument for Professor Kirmisson's conservatism. In answer to a question as to the use of passive movements in a sensitive joint, he said avoid all rough and violent movements, and if gentle movements are painful desist. "If you wish to ankylose a joint, hurt your patient." The writer feels under great obligation to Dr. Calot, Dr. Redard, Professor Kirmisson not only for their kindness and many personal attentions, but for the many valuable ideas he received from them.

Henry Ling Taylor.

Medical Contingent Fees.

Chicago, Aug. 26, 1903.

To the Editor:—In the August 22 issue of The Journal of the American Medical Association is an account of a damage case recently tried in a Colorado court which furnishes The Journal with an item for editorial comment under the heading "Medical Contingent Fees." It was admitted by the physicians for the plaintiff that the fees were contingent, that is, that they were to receive a certain percentage of the amount recovered for their services. The attorneys for the defendant corporation made the most of this admission and took the ground that it was contrary to good policy and morals. The physicians claimed that the transaction was an innocent one, that as the injured person was poor she was allowed to contract to pay her bill in this way.

Such a case as this brings up the whole vexed question of medical expert testimony, which furnishes such a fruitful theme for medical addresses and articles. Some few years ago the writer of this letter examined one of the yearly volumes of the *Index Medicus* and found 252 titles dealing with various phases of this problem.

The compensation of the medical expert witness is one of some difficulty. In certain states of the union it has been held that an expert, meaning by that one who gave open evidence and of necessity who had to specially qualify himself to

advise the court in such matters, was entitled to a fee commensurate with the time and effort necessary. Other courts have held, notably Illinois, that an expert medical witness could not refuse to testify because he had not been compensated. The courts in this state, in accordance with that of most states which have rendered decisions along this line, have held that while the physician or other expert could not refuse to testify providing he had an opinion, yet there was no way in which he could be compelled to form an opinion. He could not be made to examine facts nor to consult books nor, indeed, to set his mental machinery in operation so that he would have an opinion on a given set of facts. It will be seen that such a limitation of the decision practically makes it impossible to get expert testimony in our courts unless it is paid for. In almost every case to be of much value a physical examination of a patient must be made or there must be a careful study of a personal history or other matters, and this will not be undertaken by a physician unless it is with the understanding that he is to be compensated for the time that is required. Primarily it will be seen that all courts have recognized the necessity of opinion testimony and the fact that it requires time and effort to prepare it, and for this reason the one who gives it is entitled to a higher compensation than ordinary witness fees. Cases occasionally arise like that which is commented on by THE JOURNAL, in which a poor person is a litigant. It is probable that he can not pay his physician for the medical services, and if he is able to do that, there are many worthy litigants who would not be able to adequately compensate experts for going into court to properly present their case. It is manifestly optional with the physician whether he shall give a person credit for the amount of his fees. If he does so, and the person is very poor, it is evident that his compensation will depend on the fact of recovery. This is an unavoidable conclusion growing out of the nature of the transaction.

The chief objection against the method followed in the Colorado court is that the physicians agreed to take a certain percentage of the amount recovered. This is clearly bad practice; the amount of time required in preparing a case and in testifying is not greater where a large verdict is recovered than where a small one is obtained. The charge in all such cases should be for time, and should be based on the amount which the physician receives for similar service in which the fee is not contingent. If the amount of the fee is agreed on beforehand, there surely can be no objection if the physician chooses to wait for his fee. But to make the amount of the fee depend on the amount recovered, that gives the transaction the character that it ought not to have. On the other hand, to insist that every plaintiff should pay his expert witnesses for their services before they were allowed to testify would throw a burden on many worthy plaintiffs which in many instances would prevent their properly presenting their cases in court.

The whole subject of expert testimony in general and of medical expert testimony in particular is one that is sadly in need of revision. The enormous increase in personal injury litigation, the character of attorneys engaged in this class of work, and the kind of medical testimony which is frequently heard in our courts can not but lead to the view that some change in the near future will be necessary. Just what that change ought to be it is difficult to say. Of necessity there must be some statutory alteration, but these changes should be made with the utmost care, as any interference with the practice of our courts in a drastic manner is often more harmful than beneficial.

HAROLD N. MOYER, M.D.

The Alleged Cure for Lockjaw.

CHICAGO, Aug. 29, 1903.

To the Editor:—Through an error, I gave the wrong quantity of sodium chlorid in the formula which I used in the case of tetanus, described in THE JOURNAL, Aug. 29, 1903, page 566. The strength given is not dangerous, but is not advisable. The correct formula is:

R.	Sodii chloridi	3	656+
	Sodii sulphatis	10	06+
	Sodii citratis	3	364+
	Calcii chloridi	0	136+
	Aquæ	1000	00

The formula preceding this—the m/8, etc., formula—was correct. S. A. MATTHEWS, M.D.

State Boards of Registration.

Indiana Examination Questions.—The following were the questions used for the examination of candidates to practice medicine at the semi-annual examination of the Indiana State Board of Medical Registration and Examination, at Indianapolis, July 14 to 16, 1903, as furnished by Dr. W. T. Gott, Crawfordsville, secretary.

ANATOMY.

1. Describe the palmar fascia. 2. Give the origin, course and distribution of the internal iliac artery. 3. Give the names of the muscles of the palmar region. 4. Describe an artery. 5. Give the relation of the ureters to the pelvic organs in the female. 6. What abdominal viscera has ligamentous attachment to the diaphragm, and give the names and location of the ligaments? 7. Give the names and a description of the lobes of the lungs. 8. Describe the ligaments of the uterus. 9. At what situation can the subclavian artery be compressed from the surface? Give the anatomic relations that make this possible. 10. Name the muscles of the larynx.

PHYSIOLOGY.

1. Describe the pulmonic circulation. 2. Define (*a*) anastomosis, (*b*) metabolism, (*c*) anabolism, (*d*) catabolism. 3. What is the composition of the chyle? 4. Describe the lymphatic circulation. 5. What is the normal amount of urine voided by an adult in twenty-four hours, and what physiologic conditions cause a variation from this amount? 6. How would you proceed to make a blood count? 7. What are the five chief functions of the stomach? 8. Describe the nerve control of the urinary bladder. 9. What are the chief factors concerned in stimulating the secretion of gastric juice? 10. How would you make a quantitative analysis of the gastric juice?

OBSTETRICS.

1. Give causes, symptoms and treatment of inversion of the uterus. 2. Name one or more causes of hour-glass contraction of the uterus. Give treatment. 3. State most common cause of morbid retention of the placenta. 4. When should cesarean section be performed? 5. Give probable cause and treatment of puerperal mania. 6. Give treatment of puerperal septicemia. 7. Describe the kyphotic pelvis. 8. How long should the mother keep her bed after labor? 9. Describe Sylvester's method of artificial respiration. 10. State best method of inducing premature labor when it is designed to save the child's life.

GYNECOLOGY.

1. Name the physiologic periods of woman. 2. Give the principal procedures in local treatment. 3. Give preparation for aseptic abdominal operation, (*a*) preparation of the operator and assistants, (*b*) preparation of the instruments, etc., (*c*) preparation of the patient. 4. Define hypodermoclysis, giving technic of operation. 5. Give etiology, pathology, diagnosis and treatment of acute metritis. 6. Give indications for curettage and describe operation. 7. Give indications for hysterectomy and describe operation. 8. Give differentiations of tubercular and gonorrheal cystitis. 9. Give differentiation of renal and ovarian cysts. 10. Give diagnosis and operation for urethrovaginal fistula.

MATERIA MEDICA AND THERAPEUTICS (REGULAR).

1. Name the route by which medicinal agents may be introduced into the organism. 2. Name a medicinal agent which (*a*) raises blood pressure, (*b*) lowers it, and give the physiologic action of each. 3. Name a medicinal agent which increases the renal function, and give an indication for its use. 4. Name a medicinal agent which increases the function of the skin, and give an indication for its use. 5. Define (*a*) decoction, and (*b*) infusion. 6. Give the derivation of quinin and its therapy. 7. How does ergot arrest uterine hemorrhage? 8. Write a prescription for an expectorant suitable for the first stage of acute bronchitis. 9. Write a prescription for a general tonic. 10. Write a prescription for an emetic.

MATERIA MEDICA AND THERAPEUTICS (ECLECTIC).

1. Name two therapeutic remedies, one of which will contract the pupil and the other dilate it. 2. Give indications when you would give the following remedies, stating dose of each: Asclepias; 3, oenantha: 4, solanum car; 5, hydrastis; 6, cuprum; 7, colocynth; 8, apocynum. 9. Give indications for an acid—an alkali. 10. Write a prescription for an irritative cough, such as is often found associated with measles.

MATERIA MEDICA AND THERAPEUTICS (HOMEOPATHIC).

1. Chloroform—give therapeutic action. 2. Chimaphila umbellata—give habitat and indications for use. 3. Chelidonium—name three special centers of action. 4. Carbo-vegetabili—give therapeutic individuality. 5. Capsicum annuum—give therapeutic individuality. 6. Cantharides—name special centers of action. 7. Cannabic sativa—give anecdote and special centers of action. 8. Bryonia alba—give therapeutic individuality. 9. Pharmacology—define. 10. Kali bichromicum—give effects on mucous membranes.

THEORY AND PRACTICE OF MEDICINE (REGULAR).

1. Give predisposing cause, pathology, symptoms and prognosis of arteriosclerosis of the cerebral arteries. 2. Give predisposing cause and symptoms of cerebral hemorrhage. 3. Give exciting

cause and physical signs of croupous pneumonia. 4. Give predisposing cause and treatment of pulmonary hemorrhage. 5. Give physical signs of pleuritic effusion. 6. Give exciting cause, symptoms and treatment of typhoid fever. 7. Give common cause, symptoms and treatment of gastrointestinal catarrh in infants. 8. Give exciting cause, symptoms and pathology of epidemic cerebrospinal meningitis. 9. Give pathology and diagnosis of Bright's disease of the kidneys. 10. Give diagnosis and treatment of cystitis.

THEORY AND PRACTICE OF MEDICINE (ECLECTIC).

1. Give diagnosis, complications and sequela of scarlatina. 2. Give etiology, pathology and treatment of pericarditis. 3. Give treatment of a child 2 years old who has taken one-half grain morphia sulphas. 4. Give treatment of chronic tonsilitis and adenoids of the pharynx. 5. Give etiology, diagnosis and treatment of Addison's disease. 6. Give treatment for la grippe. 7. Give causes and treatment for chorea. 8. How would you treat a case of arsenical poisoning? 9. Give pathology and diagnosis of mitral stenosis. 10. Give cause and treatment for uremic poisoning.

THEORY AND PRACTICE OF MEDICINE (HOMEOPATHIC).

1. Define Hodgkin's disease. 2. Give diagnosis and morbid anatomy of diabetes mellitus. 3. Give etiology and diagnosis of nephritis. 4. (*a*) What is an aneurism? (*b*) Give the physical signs of aneurism of the aorta. 5. Give symptoms and treatment of arteriosclerosis. 6. Define and give treatment of enuresis. 7. State common cause and treatment of endocarditis. 8. Define hydro- and pneumo-thorax. 9. Describe chronic interstitial pneumonia. 10. Give cause and morbid anatomy of cirrhosis of the liver.

CHEMISTRY.

1. What is the usual reaction of normal urine, and to what is it due? 2. Give two reliable tests for albuminuria. 3. Give the antidotes for carbolic acid poison. 4. What elements are found in all animal and vegetable substances? 5. What is the chemical antidote for arsenical poison? 6. If you were called to see a patient who had taken a large dose of tincture of iodin what chemical antidote would you give? 7. What is an oxidizing agent? Name three. 8. What is a reducing agent? Name two. 9. What is urea chemically? What is the average daily amount excreted in the urine? 10. Define a ptomain.

SURGERY.

1. Classify dislocation of the hip joint. 2. Give the indications for surgical intervention in gastric ulcer. 3. Give differential diagnosis between a sarcoma and gumma of the testicle. 4. Give the signs and symptoms of a fracture of the shaft of a long bone. 5. Differentiate between obstruction to the common bile duct by a gallstone and by a carcinoma of the head of the pancreas. 6. Give method of reduction of subcoracoid dislocation of the shoulder joint. 7. Give indications for trephining in fractures of the skull. 8. Give differential diagnosis between mechanical ileus and acute general peritonitis. 9. Briefly describe the treatment of strangulated hernia. 10. Give the immediate treatment for acute retention of urine from an enlarged prostate.

PATHOLOGY.

1. Describe the macroscopic and microscopic appearance of the kidney in interstitial nephritis. 2. Describe an aneurism. What condition is essential for the development of an aneurism? 3. Define (*a*) telangiectasis, (*b*) edema, (*c*) necrosis, (*d*) gangrene. 4. What is the pathology of locomotor ataxia? 5. Describe three kinds of crystals found in the urine. Under what conditions are these present?

BACTERIOLOGY.

1. How would you pasteurize milk? Why is the process repeated three times? 2. Give a method of differentiation between the tubercle and smegma bacilli. 3. How would you thoroughly disinfect your hands? 4. How would you test the blood for Widal's reaction? 5. How is it conclusively demonstrated that a certain microbe is the cause of a certain disease?

HYGIENE.

1. Define hygiene. 2. What hygienic measures are most efficient in the prevention and treatment of pulmonary tuberculosis? 3. What hygienic measures are essential to the prevention of typhoid fever? 4. What hygienic measures are essential to the prevention of gastrointestinal catarrh in children? 5. Describe the proper hygiene of the sick room?

HISTOLOGY.

1. Define histology. 2. Give histology of muscle. 3. Give histology of an artery. 4. Give histology of the skin. 5. Give histology of a pulmonary air cell.

RHINOLOGY.

1. What are the causes of fetid discharge from the nose? 2. Name the congenital deformities of the nose? 3. Mention the forms of rhinitis. 4. Give the treatment of epistaxis. 5. Give the treatment of acute coryza.

MEDICAL JURISPRUDENCE.

1. How would you distinguish between an incised wound made before and after death? 2. Define (*a*) expert witness, (*b*) ordinary witness. 3. Define rigor mortis. To what is it due? 4. What organ is generally the first to undergo putrefaction? 5. What organ is generally the last to undergo putrefaction?

OPHTHALMOLOGY.

1. How would you test acuteness of vision? 2. Give test for color blindness. 3. Define conjunctivitis neonatorum; give causes, symptoms and treatment. 4. Define iridectomy, and state under what conditions you consider the operation necessary. 5. When should enucleation be performed? Describe operation.

OTOLOGY.

1. Give topography of the sound-conducting apparatus. 2. Give method of examination of the middle ear. 3. Give etiology, diagnosis and treatment of mycosis of the external ear. 4. Give diagnosis and treatment of strictures of eustachian tube. 5. Otosclerosis —give etiology, diagnosis and treatment.

LARYNGOLOGY.

1. Give the physiology of the larynx. 2. Give the differential diagnosis of syphilitic laryngitis. 3. Give symptoms and treatment of elongated uvula. 4. Give treatment of neoplasms, of the cavity of larynx. 5. Describe edema of the larynx and give proper treatment.

DERMATOLOGY.

1. Define tinea favosa; give synonym and treatment. 2. Describe scabies and give treatment. 3. What is epithelioma? 4. Give diagnosis of lupus erythematosus. 5. Give the etiology of lichen ruber.

Maine Report.—Dr. A. P. K. Meserve, secretary of the Maine Board of Registration of Medicine, reports that at the examination held at Portland, July 8 and 9, the number of subjects examined in was 14; total questions, 106; percentage required to pass, 75; 48 applicants were examined, all of whom passed. There was also one licensed by reciprocity with New Jersey, without examination. The examination was partly oral and partly written.

PASSED.

Marriages.

S. WILSON DODGE, M.D., mayor of Fairbury, Neb., to Miss Giles.

HENRY W. WALKER, M.D., to Miss Claire Johnson of Macon, Ga., August 19.

CHARLES C. CONSER, M.D., to Miss Emily L. Baker, both of Baltimore, August 20.

EMMA L. SCHOLZ, M.D., to F. H. Aldrich, M.D., both of Belview, Minn., at Waukegan, Ill., August 18.

RICHARD ARNETT WILLIAMS, M.D., Knoxville, Tenn., to Miss Cora Ella Morgan of Memphis, Tenn., August 25.

JOSEPH V. LONGFELLOW, M.D., Urbana, Ohio, to Mrs. Vilette Ward Hopkins of Rawlins, Wyo., at Cincinnati, August 24.

Deaths.

Phenett Coe Barker, M.D. College of Physicians and Surgeons, New York, 1860, ex-president of the Medical Society of the State of New Jersey, and of the Morristown (N. J.) Board of Health; founder and medical director of the Morristown Memorial Hospital and dean of the local medical profession, died at his home, August 21, from angina pectoris, after an illness of two days, aged 68.

John Hyde, M.D. Hahnemann Medical College, Philadelphia, 1840, formerly a member of the Texas Rangers and a surgeon in both the Mexican and Civil wars, died from "senile debility," after an illness of two years, August 20, at his home in Terre Haute, Ind., aged 77. He retired from active practice about twenty years ago.

William A. Boyce, M.D. Medical College of Virginia, Richmond, 1903, of Kelford, N. C., died at the Protestant Hospital, Norfolk, Va., at which he was an interne, August 5, after an

illness of one week, from septicemia due to infection of a thumb while dressing a wound, aged 25.

Charles F. Hildreth, M.D. Harvard University Medical School, Boston, formerly surgeon at the New Hampshire State Prison, Concord, and surgeon both in the Army and Navy during the Civil War, died at Manchester, N. H., August 18, from diabetes, aged 71.

Horatio F. Mintern, M.D. Arkansas University, Little Rock, 1899, a member of the Arkansas Medical Society, and the Little Rock Medical Society, died at his home in Pendleton, Ark., August 15, from malaria fever, after an illness of several weeks.

Ira Ellis Caspar Wister Smith, M.D. Atlanta (Ga.) Medical College, 1866, died at his home in Palmetto, Ga., August 17, after an illness of several months, aged 61. He represented his county in the state legislature for several terms.

Allen R. Thompson, M.D. Albany (N. Y.) Medical College, 1899, of Troy, N. Y., while suffering from melancholia due to a long illness, committed suicide by cutting his throat at Edgemere Inn, Asbury Park, N. J., August 22, aged 48.

Jonas Deisinger, M.D. University of Pennsylvania, Philadelphia, 1867, died at his home in York, Pa., August 13, from cancer of the face, after an illness of six years, aged 70. He was a member of the York County Medical Society.

Albert H. Brown, M.D. Jefferson Medical College, Philadelphia, 1903, interne at the Home Hospital, Augusta, Me., died at the City Hospital, Augusta, August 13, from tubercular meningitis, after an illness of two weeks, aged 23.

John M. Evans, M.D. Indiana Medical College, La Porte, Ind., 1846, founder and first mayor of Evansville, Wis., and at one time a member of the state legislature, died at his home in Evansville, August 23, aged 83.

Ephraim Bateman, M.D. Jefferson Medical College, Philadelphia, 1831, the oldest physician in Cumberland County, died at his home in Cedarville, N. J., August 20, from paralysis, after a long illness, aged 73.

Newton C. Harris, M.D. Albany (N. Y.) Medical College, 1857, assistant surgeon in the 155th New York Volunteer Infantry in the Civil War, died at his home in Schuylerville, N. Y., August 6, aged 70.

Samuel W. Skinner, M.D. Yale University, New Haven, Conn., 1846, surgeon and breveted colonel for meritorious service during the Civil War, died at his home in Toledo, Ohio, August 16, aged 83.

Washington West, M.D. McDowell Medical College, St. Louis, 1866, for two years a surgeon in the Navy, and afterward a resident of St. Louis, died from apoplexy after an illness of six days, aged 73.

Richard E. Brown, M.D. Jefferson Medical College, Philadelphia, 1863, a surgeon in the Army during the Civil War, died at his home in Mount Holly, N. J., August 7, from heart disease, aged 63.

Michael F. McGrath, M.D. College of Physicians and Surgeons, New York, died from consumption at the home of his brother in Fishkill Landing, N. Y., August 11, after a long illness, aged 35.

Stephen W. Seaman, M.D. Medico-Chirurgical College of Philadelphia, 1899, died at his home in Lenhartsville, Pa., August 11, from peritonitis, after an illness of one week, aged 28.

Emma Virginia Morton Baker, M.D. Woman's Medical College, Philadelphia, for ten years assistant physician at the Maine Insane Hospital, Augusta, died recently from paralysis, aged 50.

John Gleises, M.D. Bellevue Hospital Medical College, New York, 1877, of New York City, died at his summer home Brookside, near Saratoga, from "dropsy," August 14, aged 50.

J. A. Lovett, M.D. Central College of Physicians and Surgeons, Indianapolis, 1880, died from tuberculosis at his home in Goodland, Ind., after a lingering illness, August 4, aged 64.

Nathaniel L. Bunce, M.D. Cleveland Medical College, 1851, a pioneer practitioner of Marshalltown, Iowa, died at the home of his niece in Los Angeles, Cal., August 11, aged 74.

James Curry Ford, M.D. University of Louisville, 1878, died at his home in New York City from cancer of the throat, August 22, after an illness of nine months, aged 68.

John Henry Martin, M.D. University of Maryland, Baltimore, 1862, who practiced in Baltimore until a year ago, died at his home near Aberdeen, Md., August 20, aged 69.

John Irwin Arrington, M.D. University of Nashville, Tenn., 1863, died at his home in Nashville, August 19, aged 69. He retired from active practice two years ago.

Samuel O. Bryan, M.D. Louisville Medical College, died at his home near Mooleyville, Ky., August 2, from typhoid fever, after an illness of two weeks, aged 44.

Benjamin H. Howlett, M.D. College of Physicians and Surgeons, Baltimore, 1878, died at his home in Brogueville, Pa., August 14, after a long illness, aged 56.

William Z. Morgan, M.D. Kentucky School of Medicine, Louisville, 1892, died at his home in Princeton, Ky., August 17, from paralysis, after a long illness.

William P. Sharkey, M.D. Hahnemann Medical College, Philadelphia, 1875, died suddenly from heart disease at his home in Philadelphia, August 18, aged 62.

William H. Jett, M.D. University of Louisville, 1862, surgeon in the Federal Army, died suddenly at his home in Munfordville, Ky., August 17, aged 66.

P. W. Fox, M.D. Tennessee Medical College, Knoxville, 1895, died at his home near Beaver Ridge, Tenn., August 18, after an operation for appendicitis.

Hartwell C. Tompkins, M.D. University of Vermont, Burlington, died at his home in Knowlesville, N. Y., August 5, after a short illness, aged 75.

Thomas L. Phillips, M.D. Georgia College of Eclectic Medicine and Surgery, 1891, formerly of Atlanta, Ga., died at Springfield, Utah, August 13.

C. W. Miles, M.D. Bolingbroke, Ga., died at the home of his father in Griffin, Ga., August 15, from typhoid fever, after an illness of five weeks, aged 24.

James McGarry, M.D. McGill University, Montreal, 1858, died at his home in Niagara Falls, South, Ont., August 13, from gangrene of the leg, aged 69.

Richard C. Johnson, M.D. University of Louisville, 1884, died at his home in Morganfield, Ky., July 28, from dysentery, after an illness of ten days.

John W. St. Clair, M.D. Miami Medical College, Cincinnati, died at his home in Milton, Ind., August 13, after several months' illness, aged 61.

Charles E. Pierce, M.D. Eclectic Medical Institute, Cincinnati, 1878, died suddenly from heart disease at his home in Little Rock, August 19.

James E. Brown, M.D. Memphis (Tenn.) Medical College, 1858, died at his home in McKenzie, Tenn., August 13, from heart disease, aged 68.

George Ewing Connell, M.D. Howard University, Washington, D. C., 1879, died at his home in Irwin, Va., July 28, after a long illness, aged about 60.

Furman W. Runyan, M.D. Atlanta Medical College, 1887, died at his home in Austell, Ga., August 12, from uremia, after a short illness.

William H. Poindexter, M.D. University of Nashville, 1860, died from paralysis at his home in Bells, Tenn., August 17, after a long illness.

Arthur R. Barry, M.D. University of Georgetown, Washington, D. C., 1861, died at his home in Weatherford, Texas, August 4, aged 64.

Ernst Roesel, M.D. Missouri Medical College, St. Louis, 1887, died suddenly from heart disease at his home in Pequot, Minn., August 5.

Charles F. Baker, M.D., of Rawson, Ohio, died at his home in that place, July 26, from tuberculosis, after a long illness, aged 35.

John Harrington Vandiver, Jefferson Medical College, Philadelphia, 1845, died at his home in Talladega, Ala., August 17, aged 86.

John Denison Kenyon, M.D. Albany (N. Y.) Medical College, 1857, died suddenly at his home in Westerly, R. I., August 12, aged 69.

J. N. Barnett, M.D. University of Louisiana, New Orleans, 1857, died at his home in Little Rock, Ark., August 14, aged 69.

John Hursey Pool, M.D. University of Pennsylvania, Philadelphia, 1859, died at his home in South Mills, N. C., July 29.

Humphrey G. Hendrick, M.D., of Talladega, Ala., died at the home of his brother in Eureka, Ala., August 11, aged 78.

Robert J. Dearborn, M.D. College of Physicians and Surgeons, Chicago, died at his home in Morrisonville, late in July.

Andrew J. Hartman, M.D. University of Louisville, 1881, died at his home in Myers, Tenn., August 4, aged 55.

Mary K. Gale Warren, M.D. Boston University School of Medicine, 1877, died at her home in Boston, July 31.

August Trafton, M.D., 1876, died at his home in Dixon, Cal., August 15, after an illness of six weeks, aged 78.

Gotthold Pape, M.D. New York University, 1880, died, August 1, at his home in Hoboken, N. J., aged 61.

George T. Cauthorn, M.D., died at his home in Bedford City, Va., August 8, after a long period of invalidism.

Deaths Abroad.

Emma Constance Stone-Jones, L.S.A. London 1889; M.B., C.M., Trinity College, Toronto, died recently at Melbourne, Victoria, Australia, aged 46. She is said to have been the first qualified woman practitioner in Australasia.

Dr. Karl Hofmann, professor of physiology and anatomy at Leyden, aged 62.——**Dr. Ladreit de Lacharriere** of Paris, founder of the *Annales des maladies de l'orcille et du larynx*, and honorary chief of the National Institute for Deaf Mutes. ——**Dr. Chalot,** professor of surgery at Toulouse.——**Dr. Jean Roger,** inspector general of the conseil sanitaire maritime et quarantenaire in Egypt.

Carl Maydl, M.D., professor of surgery at Prague, died at his country seat, August 12, from the effects of heart disease, aged 50. Maydl commenced his career as assistant to E. Albert and accompanied the latter from Innsbruck to Vienna. His monographs on subphrenic abscesses and jejunostomy are now classics, and he succeeded in accomplishing what John Simon and Thiersch had only partially realized, that is, a permanent communication between the bladder and rectum in cases of exstrophy of the bladder. He had been long at work on a Manual of Special Surgery, and the first part has been published.

Miscellany.

THE ST. LOUIS EXPOSITION.

Plans for the Elaborate Pathologic Exhibit—Hospitals to Show Details of Their Operation.

THE HOSPITAL EXHIBIT.

The hospital exhibit of the St. Louis Exposition, 1904, is to be in the department of social economy, under the section of charities and correction. This exhibit will be displayed in the Palace of Education and Social Economy, which has a very prominent location.

Here are to be shown models of grounds and buildings, architectural drawings, photographs, charts and statistics relating to the hospital and its management. The exhibit is divided into the following subjects for elaboration by different hospitals, dispensaries, nursing schools, etc.:

1. Classification of disease.
2. Cause of disease.
3. Prevention of disease.
4. Relation of disease to crime and pauperism.
5. Evolution of the doctor.
6. Gallery of eminent physicians and surgeons.
7. Relief on the battlefield.
8. Evolution of general hospital.
9. Architecture of general hospital.
10. Model operating room.
11. Sterilizing, anesthetizing and drug rooms.
12. Diet kitchen.
13. Clinical laboratory.
14. Pathologic laboratory.
15. Pathologic exhibit (a scientific medical exhibit).
16. Display of medical instruments.
17. Ambulances.
18. Ambulance adjuncts.
19. Emergency hospitals.
20. Infectious hospitals.
21. Hospitals for consumptives.
22. Hospitals for deformities (instruments and appliances).
23. Ear and eye infirmaries.
24. Maternity hospitals.
25. Hospitals or wards for the care and treatment of inebriates.
26. Hospitals for the treatment of morphin, tobacco and other such habits.
27. Other special hospitals.
28. Leper colonies.
29. Hospital construction.
30. Sanitariums.
31. Medical aid by missionaries.
32. Dispensaries.
33. The evolution of the nurse.
34. Gallery of famous nurses.
35. The visiting nurse.
36. Nurses' handiwork.
37. Training schools for nurses.
38. Gallery of eminent philanthropists.

THE PATHOLOGIC EXHIBIT.

Some of the best pathologists and anatomists are preparing a scientific classification for a pathologic exhibit. As now contemplated diseases will be grouped according to organs. Each gross specimen (as lung, heart, brain, liver, etc.) will be duplicated by a normal anatomic specimen. Each pathologic specimen will be accompanied by a microscopic slide where possible, showing the micro-organism causative in the production of the disease. When dissection of the normal would elucidate the medical or surgical field, the same will be present, dissected properly and preserved and mounted in the most approved way. Models, photographs and statistics will accompany the pathologic specimens.

The department announces that the object of the pathologic exhibit is to indicate as succinctly as possible the rise, progress and present status of our knowledge of disease in man and the domestic animals. The choicest pathologic specimens from the various medical centers of the United States, when properly exhibited according to the final plans, will form an object lesson in this department of science never before seen in this country. The exhibit will represent the work of specialists in histology, embryology, bacteriology, physiology and dissection. To make the exhibit more effective and at the same time more utilitarian for the physician, library and reading-room facilities are to be found in connection with the same. To insure greater interest in diseased tissues and organs, a series of dissections illustrating many points in the normal anatomy of man and the domestic animals will help to complete the exhibit.

It is deemed wise to classify (1) in general; (2) in particular. In the former, organs irrespective of disease are grouped; in the latter, the organic classification is subordinate to diseased structures. As previously stated, according to the special classification, diseases or diseased parts regardless of organ or part of body in which found, characterize this classification, such as tumors, fractures, skin diseases, etc.

Exhibitors are not required to comply with every feature of the arrangement set forth under the general classification, although this is earnestly desired when circumstances permit. Where an exhibitor sends in, e g., a pneumonic lung only, the department will see to it that the other features, such as slides and normal anatomy, are properly cared for. Parties competing for prize dissections illustrating normal anatomy inform us of the region to be dissected.

To set forth the scheme of the general classification in its proper form let us illustrate the essential features by an analysis of one organ, as, e. g., the lung. In this department will be exhibited normal and diseased lungs arranged for study as follows:

1. Dissections showing normal human lungs.
2. Dissections showing normal domestic animals.
3. Microscopic slides, normal.
4. Pathologic specimens, gross.
5. Pathologic specimens, microscopic.
6. Cultures and culture processes.
7. Charts, devices and stereopticon views.
8. Books and reprints on anatomy, histology, bacteriology and pathology of pulmonary diseases.

Colleges, hospitals and individuals are asked to furnish approximate lists of the specimens which they will exhibit. Correspondence should be opened up at once with Alvin E. Pope, St. Louis, superintendent of the section on charities and correction.

Book Notices.

INTERNATIONAL CLINICS. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and Other Topics of Interest to Students and Practitioners by Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattell, A.M., M.D., Philadelphia, U. S. A., with the Collaboration of John B. Murphy, M.D., Chicago; Alexander D. Blackader, M.D., Montreal; H. C. Wood, M.D., Philadelphia; T. M. Rotch, M.D., Boston; E. Landolt, M.D., Paris; Thomas G. Morton, M.D., Philadelphia; James J. Walsh, M.D., New York; J. W. Ballantyne, M.D., Edinburgh, and John Harold, M.D., London;

with Regular Correspondents in Montreal, London, Paris, Leipsic and Vienna. Volume II, Thirteenth Series. Cloth. Pp. 311. Price, $2.00. Philadelphia and London: J. B. Lippincott Company.

This work, properly a serial in book form, will be found full of practical instruction, like all the others of the series which we have seen. The subjects considered in the present volume are: "The Summer Diarrheas of Children, Disease of the Pancreas, Treatment, Practice of Medicine, Surgery, Pediatrics, Obstetrics and Gynecology, and Ophthalmology," and under each of these heads are valuable papers by well-known authors, among whom may be included Professors Conn of Middletown, Conn., Cotton, Deaver, Gay, Goffe, Bouchard and Landolt of Paris, and other names hardly less familiar. These are themselves sufficient assurance of the merits of the articles, and the work, taken as a whole, is a series of brief but valuable monographic papers on the subjects that it includes.

A MANUAL OF PRACTICAL ANATOMY. By the Late Prof. Alfred W. Hughes. M.B., M.C., Edin., F.R.C.S. Edin., F.R.C.S. Eng. Professor of Anatomy, King's College, London. Edited and Completed by Arthur Keith, M.D., Aberd.; F.R.C.S. Eng., Lecturer on Anatomy, London Hospital Medical College. In Three Parts. Part III. The Head, Neck and Central Nervous System. Illustrated by 12 colored plates and 204 figures in the text. Cloth. Pp. 387. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

The same general plan is carried out in Part III as in the foregoing parts. It contains 12 colored plates and 204 figures. A notable feature of this part is the repeated reference that is made to the surgical importance of many of the structures of the head, neck and central nervous system. The surface markings of the brain is dwelt on and given due consideration. The surgical anatomy of the head receives considerable attention, and the different regions from which the lymphatic glands receive their supply are mentioned. More attention is given than in ordinary books to the anatomy of the ear, and here again many references are made to surgical procedures. The description of the spinal cord is rather brief, but the brain receives the attention it deserves. In the dissection of the cranial nerves the author claims that it is more convenient to consider the last first and the first last, and he seems to carry out the plan to apparent advantage. Altogether the division of the subject of dissection into three different parts has many advantages which would be apparent to any student trying to work and at the same time care for a large unwieldy single volume.

SELECTED PAPERS ON OPERATIVE AND CLINICAL SURGERY. By the Late William Stokes, M.D., M. Ch. (Univ. Dub.); F.R.C.S.I.; Knt., Surgeon in Ordinary to Her Majesty Queen Victoria in Ireland. Edited by William Taylor, B.A., M.D. (Univ. Dub.), F.R.C.S.I., Surgeon to and Lecturer on Clinical and Operative Surgery, Meath Hospital and Co. Dublin Infirmary. With a Memoir of the Author by Alexander Ogston, M.D., Regius Professor of Surgery, University of Aberdeen. Cloth. Pp. 484. Price, 10 Shillings. London and Dublin. Bailliere, Tindall and Cox. 1902.

This work consists of a collection of the articles written during the past thirty-five years by the late Wm. Stokes, and edited by Wm. Taylor. All the articles have appeared elsewhere in the various medical journals at the time they were written, with the exception of the two South African papers added by Mr. Taylor. Most of the chapters are so old, some of them even antedating the antiseptic era, that they can have little more than a historic value. Collectively they illustrate fairly well the progress of surgery from early Listerism down to recent times.

MEDICAL JURISPRUDENCE. A Manual for Students and Practitioners. By Edwin Welles Dwight, M.D., Instructor in Legal Medicine, Harvard University. Series Edited by V. C. Pedersen, A.M., M.D., Instructor in Surgery and Assistant Anesthetist at the New York Polyclinic Medical School and Hospital. Cloth. Pp. 249. Philadelphia and New York: Lea Brothers & Co.

This little volume is intended only as a brief compendium of the facts in connection with legal medicine which every practicing physician ought to know. As such, and as a work for students, it is not exhaustive, but in the main it gives a very fair and reliable summary of the principal facts. A notable omission, however, is that of the biologic blood test, which certainly ought to be included in every work coming out in 1903. The part devoted to insanity is necessarily brief and hardly sufficiently complete for this day. Aside from these, and possible one or two other minor points, the book is one to be generally commended.

Association News.

REPORT ON THE SCIENTIFIC EXHIBIT

Of the American Medical Association, at New Orleans, May 5-8, 1903.

By Frank B. Wynn, A.M., M.D., Chairman.

The fourth Scientific Exhibit of the Association was most successfully consummated, despite obstacles which for a time threatened a favorable outcome. The remoteness of New Orleans from sources of material and a three-month period in which to accomplish the work, cast a gloom over those deeply interested in the continued success of the movement. Too much can not be said in praise of those who came nobly to the rescue at a critical time. On the roll of honor are twenty-eight persons who labored faithfully, without money and without price, for the common good of the profession and the success of the meeting. Among them are those distinguished both in the scientific and practical fields of medicine, as well as young men fired with enthusiasm for the higher ideals of the profession.

In a perusal of the subjoined report it will be noted that 16 well-known colleges, hospitals or public institutions are represented and 11 private collections. The analytical reader will observe as conspicuous features three research exhibits and the general tendency of contributors to the grouping of specimens in illumination of particular phases of pathology. This is in response to the gradually evolved policy of the committee.

Lack of efficient demonstration has long been recognized by those having the matter at heart as the weak point of the exhibit. Many specimens extremely valuable as practical object lessons, remain impotent on the shelves unless intelligently demonstrated. As long as five years ago the writer, in a letter to THE JOURNAL, strongly advocated systematic demonstration in connection with the presentation of state society exhibits. It is just as important for national collections if the greatest degree of instructive efficiency is to be attained. It was hoped in the outset that exhibitors would see to the demonstration of their own contributions. Few, however, have been able to give so much time. The plan has also been tried of attempting to secure a large demonstration corps of medical students and young physicians resident in the place of meeting, who should alternate in escorting small delegations of visitors about the exhibit. But it was found impossible to secure a sufficient number of competent men willing to give the necessary time. The solution of this perplexing problem has come naturally in the reduction of the size of the exhibit and its specialization. In this way demonstration becomes simplified and less laborious.

The particular phases of pathology or other scientific branch of medicine illuminated in the exhibit from year to year should be varied according to the topics prominently before the profession and likely to command conspicuous attention in the Section meetings. In consonance with the ideas expressed there were shown at New Orleans very complete series illustrative of the following: Anomalies and pathologic conditions of the heart; tuberculosis in the various organs and structures of the body; amebic dysentery with sequels and intestinal lesions of tuberculosis and typhoid for purposes of differentiation; malaria; fibroid tumors; ectopic gestation; surgical diseases of the kidney; pathologic conditions of the bladder and prostate gland; renal and vesical calculi; otologic and neurologic groups. Effort was made to have these series demonstrated before the interested sections in conjunction with related papers to be read. The idea met with warm reception on the part of Section officers generally, but crowded programs made its consummation difficult of accomplishment. For the coming meeting at Atlantic City, however, it may be definitely stated that demonstrations of particular series of the exhibit will be conducted by persons of distinction, scheduled for specific hours and days on the published program.

M'GILL UNIVERSITY: GEORGE ADAMI AND M. E. ABBOTT.

1. Ruptured Tubal Gestation, Third Week.—Age 26; two full-term children, last one being 4 years of age. Menstrual history: Began at 12; regular; scanty, only lasting one and one-half days. Complaints on admission: Sudden, severe pain in the lower abdomen

and fainting on Dec. 1, 1902, lasting until operation on the third. Last regular period Nov. 15, 1902, but since then any exertion would cause flow. Nauseated two weeks and had two chills the day before operation. Pulse weak, thready, 168; respirations, 44, labored; temperature, 98 2/5. Operation Dec. 3, 1902. Abdominal cavity contained a large quantity of fluid blood. Recovery.

2. Tubal Pregnancy. Rupture in Early Weeks.—Aged 26. Last labor eight months previous. Last regular period June 13, 1900; menstrual flow from May 17 to June 3, with severe pains in abdomen, persisting until June 13, when they became very severe and collapse developed. Pulse, 115; respirations, 44. Abdominal section. Recovery.

3. Ectopic Gestation.—Specimen a five and a half months fetus, which had remained in the abdominal cavity seventeen years, having been killed by application of electricity. Fetus now represented by a mass bent on itself, the bones of vertebral column, ribs, one upper extremity and part of cranium still plainly made out. Patient aged 55. In 1885 right tube found to be seat of gestation of five and one half months. Gestation was checked by application of electricity. For eight years the patient was well, but for the past nine she has had recurring spasmodic pains, growing worse and worse. Abdominal section Dec. 13, 1902. Recovery.

4. Fetus, Sac and Tube. Ectopic Gestation, Five and One-half Months.—Patient aged 30. Complained on admission of epigastric pain, vomiting and weakness. Pulse, 160; respirations, 36; temperature, 98.8 F. Last menstruation Jan. 26, 1901. Usual signs and symptoms of pregnancy marked. During night of July 3 was seized with paroxysms of epigastric pain and vomiting, followed in some hours by a chill. On July 4 had three fainting spells. Pelvic examination revealed a soft cervix, to which was attached a firm globular mass. Neither ballotment nor rhythmic contractions could be felt. Operation July 4, 1901, revealed fetus floating in free blood in the abdominal cavity. Recovery.

5. Tubal Pregnancy. Ruptured in Third Month.—Enlarged uterus and appendages; the right tube enlarged to form tumor size of an orange; laid open to show placental tissue, fetus and cord *in situ*. Fetus apparently dead some time. Pelvic hematocele and septic peritonitis. Patient aged 32; amenorrhea and morning vomiting for three months; severe crampy abdominal pains, with bloody vaginal discharge for three weeks before death from septic peritonitis.

6-9. Ruptured Tubal Pregnancies.

10. Section Through Pelvic Organs, Showing Multiple Fibromata Uteri, with Calcification.

This beautiful exhibit was solicited as a special feature in illumination of ectopic gestation, which was one of the topics prominently considered by the Section on Obstetrics and Diseases of Women. It was the second contribution of McGill University to the Scientific Exhibit of the Association, and testifies most forcefully to the scientific spirit and friendly cooperation of our Canadian colleagues.

CINCINNATI HOSPITAL AND CINCINNATI ACADEMY OF MEDICINE: HORACE J. WHITACRE, ASSISTED BY J. C. BUTTEMILLER AND MARION WHITACRE.

In conformity with the suggestion of the committee the following contribution was arranged to illustrate chiefly one phase of surgical pathology, viz., surgical diseases of the kidney.

Nos. 11-78. Group I. Surgical Diseases of Kidney.—68 wet specimens, showing the following range of lesions: Contracted kidney; large white kidney; rupture of kidney (nephrectomy); cystic kidney (four varieties); pyelitis; hydronephrosis, from stone in ureter, from hypertrophy of prostate, from cancer of the vesical ends of both ureters, and from stricture of urethra; pyonephrosis (eight specimens); stone in pelvis of kidney (several varieties of stone); tubercular kidney; sarcoma of kidney; retroperitoneal sarcoma and carcinoma.

Especially beautiful in this group were two congenital cystic kidneys; also the series of tubercular kidneys. One specimen showed a definitely circumscribed tuberculous mass in one end of the organ; another great numbers of miliary tubercles; another multiple caseous foci varying in size from a pin-head to a large pea; a fourth was reduced to shell one centimeter thick; in a fifth the capsule formed a sac filled with caseous matter, but no demonstrable tubercular tissue; and a sixth constituted a tumor the size of a child's head.

Nos. 79-104. Group II. Calculi.—Removed from the pelvis of the kidney, from the middle of the ureter, from the vesical end of the ureter and from the bladder. Fifteen of these loaned by Joseph Ransohoff; others by J. C. Oliver, N. P. Dandridge and William Judkins.

The specimen of pyonephrosis with stone in the pelvis of the kidney presents some features of unusual interest. First a stone weighing six and one-half ounces was removed by operation; four weeks later the kidney was removed, as the patient did not improve. Later it was found that the kidney of the opposite side was totally destroyed and contained a large stone.

Nos. 105-110. Specimens of Ectopic Gestation.—Presented by Charles L. Bonifield and John Miller.

No. 111. Embolism of Left Coronary Artery.—This case occurred in the practice of Paul Millikin of Hamilton, Ohio. The patient, a young man, died with marked symptoms of angina pectoris. The necropsy revealed a ruptured chorda tendineæ protruding from the mouth of the vessel, while on the end within the artery was a small thrombotic mass completely occluding the vessel.

Not only from a pathologic standpoint was this collection most excellent and instructive, but in an artistic way as well. Most were Kaiserling preparations, mounted with great care. It was the third contribution from Cincinnati to the National Exhibit and constitutes a forceful example of the stimulating effect of the exhibit in awakening local interest in practical pathology. Three years ago the showing of Cincinnati at St. Paul was meager; at Saratoga decided improvement was noted; and the superb collection presented at New Orleans reflected great credit on the profession of Cincinnati, and gives proof of substantial progress in the field of practical pathology.

MEDICAL DEPARTMENT TULANE UNIVERSITY: O. L. POTHIER.

Nos. 112-219. Photographs.

This excellent array of photographs was designed to show more particularly the diseases prevalent in the colored race, such as keloid, leucoderma, elephantiasis, etc. One beautiful picture was of a most extensive case of pemphigus in the negro, followed by cure. Another photograph was of a case of pseudohermaphrodism, presenting a most interesting history. The individual was 45 years of age when admitted to the female wards of the Charity Hospital of New Orleans. He had always supposed himself a woman, and had always lived among women. It was by accident that the physician in charge discovered that the condition was simply hypospadias. The man refused to put on male clothing, and when transferred to the male wards took the first opportunity offered to run away.

No. 220. Double-Headed Monster.—A noteworthy specimen from a colored woman. She had traveled some distance from the country with one of the heads born. When admitted to the Charity Hospital the case was supposed to be one of twins which had become locked. As the first child (?) was dead, amputation of the head and shoulder was performed. Recognition of the monster came only with the birth of the other part. An examination of the monster revealed four lungs, two hearts, two stomachs, two duodenums for a distance of about an inch, after which they fused, and single intestine. There were two kidneys, one liver, one spleen, and the organs of reproduction single. The body showed two heads, two spinal columns, two spinal cords, fusion taking place at the sacrum, two arms and two legs.

No. 221. Elephantiasis of Penis.—The subject was a negro who presented no other evidence of the disease. The organ measured twelve inches in length and fourteen in circumference.

Nos. 222-235. Miscellaneous Gross Specimens.

The collection gave ample evidence of the richness of the field for the study of pathologic conditions more or less characteristic of the negro. New Orleans offers in the Charity Hospital a wealth of material which under the present efficient pathologic dissection will yield valuable results in the near future.

MEDICAL DEPARTMENT, UNIVERSITY OF TEXAS: W. S. CARTER.

Nos. 236-255. Apparatus.—Some twenty pieces for physiologic experimentation, largely constructed in the Harvard laboratories under Professor Porter, and partly devised in the laboratories of the University of Texas.

Nos. 256-315. Tracings.—Six books, very neatly made by students of the university and grouped as follows:

(*a*) Frog's heart and circulation: showing influence of cold and warm physiologic salt solution on heart beat.

Peculiarities of heart muscle: staircase contractions after first ligature of Stannius; latent and refractory periods; maximum contraction with minimum stimulus; separate contractions from tetanizing current, etc.

Innervation of heart: augmentation of heart beats from stimulation of sympathetic; stimulation of vagi and crescent normally and after application of nicotin; crossed action of muscarin and atropin on ganglia of heart, etc.

Blood pressure in aorta: effect of cardiac inhibition of reflex vasoconstriction by stimulating a sensory nerve and the fall of pressure from destroying spinal cord.

(*b*) Circulation in mammals: showing effect of bleeding and transfusion on blood pressure. Effect of chloroform and ether respectively on the circulation and respiration; influence of artificial respiration after respiration stops.

The effect of stimulating the great splanchnic in the dog before and after cutting the vagi; stimulation of the (*a*) central and (*b*) peripheral ends of the cut splanchnic.

Stimulation of the depressor nerve before and after section of the vagi (rabbit).

Effect of adrenal extract, of peptone, of cutting spinal cord high up, Traube-Hering curves, etc.

(*c*) Respiration: effect of inflation and collapse of the lung on respiratory activity; apnea; stimulating a sensory nerve; stimulating the trigeminus and superior laryngeal (causing inhibition); stimulation of the vagi with feeble and strong currents; effect of section of vagi on the frequency and depth of respiration, etc.

(*d*) Muscle and nerve experiments: showing myogram with drum at fast speed and tuning fork waves making hundredths of a second; extensibility and elasticity of muscle; effect of heat and cold on myogram; heat rigor; effect of load on myogram; influence of veratria and suprarenal extract on muscle twitch; analysis of tetanus, showing tracings with 8, 16, 24, 40 and 50 stimuli per second; fatigue curves; electrotonus—effect of galvanic current on the irritability and conductivity of nerve, etc.

The foregoing is sufficient to acquaint the reader with the fact that physiology as taught at the State University of

Texas is abreast of the leading institutions of the country and keeping pace with the commercial progress of the "New South."

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL: WINFIELD S. HALL.

No. 316. Frog-Board Myograph.—An inexpensive and convenient myograph, an improved ergograph, especially adapted to work in general physiology and pharmacology. Its advantages over other similar instruments are: 1. The muscle-nerve preparation can be made in at most one-fourth the time required for the classic preparation. 2. The muscle and nerve are not exposed to atmospheric changes. 3. The circulation of the tissues is not disturbed. This has the advantage (*a*) of permitting the study of the action of drugs on muscle tissue under normal conditions, (*b*) of studying fatigue without the accumulation of fatigue products under abnormal conditions.

No. 317. Manometer Tambour.—A modification of the classic manometer apparatus. A small tambour was joined to the distal end of the manometer by a piece of pressure tubing and supplied with a delicate tracing lever, capable of magnifying the movements of the membrane ten to twenty times, as desired. With the surface of the tambour not larger than 15 mm. and the mercury meniscus not less than 3 mm. in diameter, the most beautiful arterial pressure tracing can be obtained, showing not only the respiratory and percussion waves, but the dicrotic wave clearly superimposed on each cardiac wave.

Medical Organization.

MEDICAL ORGANIZATION METHODS AND BENEFITS.

J. N. M'CORMACK.

(Continued from page 569.)

HOW DISSENSIONS GROW.

His location chosen, say in a community where there are two physicians already, he is fortunate if he is not met at the threshold, the most sensitive and impressionable period of his life, with ill-concealed sneers, or complete ostracism by those already established in practice, which will grow if he succeeds, or rapidly disappear if he proves a failure. With time, and an arm's length acquaintance which can not be avoided entirely, he will probably learn that one or both of his professional neighbors practically dropped their studies at graduation; that they receive little or no new literature except the free copy advertising journals; that they have no proper equipment for the emergency surgery they must do, or pretend to do, while time was habitually given over to petty professional bickerings and contentions sufficient to have made both of them scholars of no mean attainments in medicine as well as in general knowledge, had it been utilized in single, or better still, in joint study. Although they constantly need each other's advice and help as no other men ever can do, he is likely to find that this spirit of envy and jealousy, pitched on a plane low almost beyond conception, not only deprive them of these, but so divides them and impresses the community as to greatly lessen the respect and confidence due both of these otherwise worthy men, as well as the great profession which they alone represent in that community. He will find that they often quarrel about diagnoses in which both were wrong; about patients who would not pay either of them, or about violations of the code which neither of them have read; that each is afraid to collect his hard-earned fees for fear the other will inherit some of his offended patrons; that ambition for excellence in surgery or other special work is dwarfed by the fact that one will send for consultation, or send his surgery, to a distant town or city rather than ask the assistance of his neighbor, and that even their families are so estranged as to be deprived of social relations and pleasures of which both are most deserving. In a word, our graduate is likely to find that this canker of envy and jealousy which clings to our otherwise noble profession with such tenacity, and blights and curses, and curses and blights, all to which it clings, not only bars or makes all advancement difficult, but so interferes with all the social and other interests and purposes of the profession as to destroy his ideals of life. Gradually the dominant bias of his college life begins to assert itself, and with no society influence to correct the evils, or even to furnish him the opportunity of learning that his competitors are well-meaning men personally, who were stunted and misshapen by the same process to which he is being subjected, our graduate, whose horizon was probably never large, but certainly susceptible of enlargement, will be in great danger of becoming the victim of his environments, and grow smaller and smaller with the years, until he becomes a physician only in name.

POVERTY AND OTHER ILLS CAUSED.

It is mainly this spirit and the resulting conditions which cause so much poverty in the profession, interfering with it in every business aspect, just as the loss of public respect and confidence directly traceable to it accounts for most of the difficulties in securing needed medical and health legislation and in enforcing such laws when enacted.

And this is no fancy sketch. Let him who doubts its fidelity to truth try to induce some physician of the same community, somewhere outside of the long organized sections, or the occasional nature's nobleman, as an exception to prove the rule, to speak in real kind and unstinted praise of each other. It has become such a custom for physicians to refer to each other in terms of detraction, or by damning with faint praise, that one is disappointed in going to a strange community not to hear it, and always, whether in the country between two physicians, or in the city between two factions, whether done with the clumsiness of the boor or the finish of the scholar, back of it may be seen the same hideous monster of personal envy and jealousy which has dominated our profession for ages like one of the demons of mythology.

That such glaring and hurtful evils should fasten themselves on a great, noble and really learned profession like ours, generation after generation, and make its dissensions a by-word and term of reproach in common speech and literature, has been difficult for many to understand. As men and citizens, its individual members will bear favorable comparison with any and all other classes. They do more for the poor, more actual Christian charity, every day in the year than all the churches, preachers, Christian Endeavors, Epworth Leagues and similar institutions combined. They can and do live in peace and amity with everybody in the community except each other.

REASONS FOR THESE CONDITIONS.

On investigation it will be found that this is a condition common to all unorganized vocations whose members lead segregated lives. It is a recognized fact in history that the inhabitants of islands are suspicious and sensitive. This seems to be equally true of most individuals who live apart from their fellows from any cause. Until the prevalence of the community-of-interests idea induced systematic organization, the rivalry between local bankers was proverbial, and until the day of ministerial associations, with the weekly meetings, and opportunity for acquaintance and agreement as to matters of policy and public concern, and at least decent and respectful tolerance as to essentials, the condition of the ministry was worse. Instances might be multiplied indicating each similar vocation. On the other hand, lawyers have always lived together in peace and plenty. This is not because they are better men, or that their profession is a broader one, but for the reason that in the ordinary pursuit of their calling they are brought into constant contact with each other, come to know each other, and, being worthy men in the main, mutual respect and tolerance for each other's faults and shortcomings grow up naturally and unconsciously. In addition, every term of court is a free training school, with a constant and almost ideal attrition of mind against mind. Those who do not study go to the rear and lose out. Those who do not polish off their angles get them knocked off. After the hard words and fierce conflicts, sometimes unavoidable when earnest men contend over serious and weighty matters, which physicians would treasure up and pout about for years, rolling and trolling them on the tongue as dainty morsels long after they were barred by every statute of limitation, being encouraged to do so by other kindred spirits and custom, lawyers or their professional friends usually effect an immediate reconciliation, go arm-in-arm to the nearest cafe to bury the chance enmity in a lunch, julep or cocktail, and are only the better friends for having tried each other's metal.

(To be continued.)

Harrison County (Miss.) Medical Society.

This society met at Biloxi, August 12, and perfected reorganization.

Delaware County (Ind.) Medical Society.

At a meeting held in Muncie, August 13, the society voted to reorganize under the plan recommended by the American Medical Association.

Leon County (Fla.) Medical Association.

This association was organized at Tallahassee, August 7, with the following officers: Dr. William E. Moor, president; Dr. Henry E. Palmer, vice-president, and Dr. C. M. Ansley, secretary, all of Tallahassee.

Yolo County (Cal.) Medical Society.

Pursuant to call of Dr. Walter E. Bates, Davisville, the physicians of Yolo County met at Woodland, August 13, and organized a county medical society, electing Dr. Walter E. Bates, Davisville, president, and Dr. Fairchild, secretary.

Boone County (Iowa) Medical Society.

Medical men of Boone County met at Boone, August 18, to organize a county medical society in affiliation with the state and National organizations. Dr. William L. Pollock, Boone, was made temporary chairman, and Dr. Myers, temporary secretary.

Codington County (S. Dak.) Medical Society.

On August 5, fourteen physicians met at Watertown and took the first steps toward the organization of a county medical society to be in affiliation with the state and National organizations. Permanent organization is to be effected September 15.

Orange County (Texas) Medical Association.

Dr. Benjamin F. Calhoun, Beaumont, councilor for the Southeast District, met the physicians of Orange County at Orange, August 4, and delivered an address on organization, after which the society was reorganized in conformity with the regulations of the state and National associations.

Hill County (Texas) Medical Association.

The Hill County Medical and Surgical Association met at Hillsboro, August 12, and reorganized as the Hill County Medical Association, in accordance with the requirements of the new state organization. The officers are Dr. George D. Bond, president, and Dr. J. M. Martin, secretary, both of Hillsboro.

Lamar County (Texas) Medical Association.

This association was recently organized at Paris with the following officers: Dr. W. G. McCuistion, president; Dr. John B. Chapman, vice-president; Dr. Alexander H. Lindsay, secretary; Dr. James M. Hooks, treasurer; Drs. Thomas Moody, and Joseph F. Clark, all of Paris, and John F. Dyer, Chicota, censors.

Floyd County (Ga.) Medical Society.

On August 4 this society was organized at Rome, in accordance with the plan suggested by the American Medical Association. The officers elected are: Dr. Ross P. Cox, Rome, president; Dr. Levi P. Hammond, Rome, vice-president; Dr. James C. Watts, Cave Spring, treasurer, and Dr. William J. Shaw, Rome, secretary.

Jackson County (Texas) Medical Association.

On July 28 the physicians of the county met at Edna and organized a county medical society, with the following officers: Dr. Joseph M. Richmond, Edna, president; Dr. J. C. Dobbs, Ganado, vice-president; Dr. Oliver H. Radkey, Manor, secretary and treasurer, and Drs. Robert E. L. La Bauve, Edna, John L. Lincecum, Victoria, and W. H. Minton, censors.

Collin County (Texas) Medical Association.

The Collin County Medical Association, at its meeting in McKinney, August 11, perfected its reorganization under the auspices of the state and National associations, with the following officers: President, Dr. James N. Mendenhall, Plano; vice-president, Dr. Austin T. Bryant, McKinney, and secretary-treasurer, Dr. Orville H. Kirkpatrick, McKinney.

Perry County (Miss.) Medical Society.

The physicians of Perry County met at Hattiesburg, August 20, and organized a county medical society, with the following officers: President, Dr. Charles W. Bufkin; vice-president, Dr. Robert B. Stapleton; secretary and treasurer, Dr. John J. Stevens; censors, Drs. Theophilus E. Ross and Walter W. Crawford, Hattiesburg, and Dr. Prentiss A. Carter, Augusta.

Black Hawk County (Iowa) Medical Society.

At a meeting of physicians of the county at Waterloo, August 17, Dr. Elmer E. Dunkelberg was elected chairman and Dr. Edward R. Shannon, secretary, both of Waterloo. After the plan of reorganization recommended by the American Medical Association had been explained the society was organized with the following officers: President, Dr. Elmer E. Dunkelberg, Waterloo; vice-president, Dr. John H. Crippen, Waterloo; secretary, Dr. William H. Bickley, Waterloo; treasurer, Dr. Will L. Hearst, Cedar Falls, and censors, Drs. Daniel W. Crouse, Waterloo, Frank H. Cutler, Cedar Falls, and M. R. Balliet, Laporte City.

Organization Work in Texas.

Although Texas is our largest state territorially, and its fifteen councilor districts cover immense and sparsely settled areas, some of them remote from railroads, the report of organization work is of the most encouraging nature. The counties, of which there are about two hundred and forty, are rapidly organizing, and it is safe to say that a majority of the 5,000 legalized physicians of the state will be officially represented in the house of delegates at the next annual meeting of the state association. This gratifying situation is due in some measure to an aroused general sentiment, which favors without qualification the splendid scheme of organization proposed by the American Medical Association. When occasion demands the councilor receives the active support of the best men of his district. They go with him to remote counties, and assist in their organization, at great sacrifice to their private interests. Moreover, the experienced and able secretary of the state association, who is serving in Texas with conspicuous ability the higher ends and aims of the great enterprise to which the medical profession of the United States is committed, watches and aids every important detail of the work of each district, and keeps the entire situation intelligently open to the profession. Let states less hopeful, but more fortunate in respect of location and means of communication, take courage and push along the good work in like manner.

Societies.

COMING MEETINGS.

Medical Society of the Missouri Valley, Omaha, Sept. 14-15.
Medical Society of Virginia, Roanoke, Sept. 15-17.
Medical Society of the State of Pennsylvania, York, Sept. 22-24.
American Association of Obstetricians and Gynecologists, Chicago, Sept. 22-24.
Colorado State Medical Society, Denver, Oct. 6-8.
Medical Association of the District of Columbia, Washington, Oct. 6.
Idaho State Medical Society, Boise, Oct. 8-9.
Mississippi Valley Medical Association, Memphis, Tenn., Oct. 7-9.
Vermont State Medical Society, Bellows Falls, Oct. 15-16.
New York State Medical Association, New York City. Oct. 19-22.

North Texas Medical Association.—This association has filed amendment to charter embracing the counties of Fannin, Hunt, Grayson, Tarrant, Johnson, Cooke, Delta, Hopkins, Kaufman, Rockwall, Collin, Denton, Dallas and Ellis.

Wabash County (Ill.) Medical Society.—This society met at Mount Carmel, August 4, and elected Dr. W. B. Moon, Bellmont, president; Dr. George C. Kingsbury, Mount Carmel; Dr. John B. Maxwell, secretary, and Dr. Sereno W. Schenck, treasurer, all of Mount Carmel.

Dallas County (Ala.) Medical Society.—At a meeting held August 6 in Selma, Dr. Henry D. Furniss, Selma, resigned as president, and was made an honorary life member; Dr. Barney

B. Rogan, Selma, secretary, was elected president, and Dr. Ira C. Skinner, Selma, secretary.

Mississippi Valley Medical Association.—The twenty-ninth annual meeting will be held in Memphis, Tenn., October 7 to 9, under the presidency of Dr. Edwin Walker, Evansville, Ind. The sections will meet at the Gayoso and the Peabody. Dr. John L. Jelks is chairman of the committee of arrangements.

Southern Minnesota Medical Association.—At the annual meeting in Winona, August 6, the following officers were elected: Dr. Christopher Graham, Rochester, president; Drs. William F. Milligan, Wabasha, and Frank W. Dimmitt, Red Wing, vice-presidents, and Dr. William T. Adams, Elgin, secretary and treasurer. The 1904 meeting will be held in Rochester.

BRITISH MEDICAL ASSOCIATION.

Seventy-first Annual Meeting, held at Swansea, Wales, July 28 to 31, 1903.

(By Our Special Representative.)

(Continued from page 572.)

Ocular Changes in Relation to Renal Disease.

MR. EDWARD NETTLESHIP contributed a paper on this subject. Although much is already known about the eye changes in renal disease, he said information is still needed, both from ophthalmologists and physicians, on several points, and he suggested the following heads as furnishing matter suitable for discussion:

1. Does albuminuric retinitis ever occur in primary acute nephritis other than the kidney affection of pregnancy?

2. Cases of retinitis from lardaceous disease of the kidneys and from nephritis due to inflammation of the bladder, ureter, or pelvis of the kidney should be recorded.

3. The retinitis of pregnancy. Cases of this are desired: (a) In which it is known that the kidneys were diseased before the first pregnancy; (b) in which there is positive evidence that they were sound. It seems that most of the cases of pregnancy retinitis occur between the ages of 30 and 40, after several pregnancies and several attacks of pregnancy dropsy, and that the prognosis for life is better than in ordinary renal retinitis. These facts harmonize with the other evidences that the kidney disease induced by pregnancy is a peculiar and often recoverable affection. All cases of pregnancy retinitis should be examined for signs of established chronic nephritis. The propriety of inducing premature labor may depend partly on the diagnosis in this respect.

4. Age and sex. If all cases of renal retinitis (except those due to pregnancy) are counted together without reference to age the males are found to be nearly twice as numerous as the females, the proportions being about the same as for chronic nephritis. But when the retinitis occurs early in life the sex proportions seem, from the scanty material available for comparison, to be almost reversed. All cases of renal retinitis in young subjects should be recorded.

5. Recognizing two chief factors in the production of renal retinitis—the state of the blood and the state of the retinal blood vessels—all cases are asked for in which a condition of visible disease in the retinal arteries without evidence of kidney disease has been followed sooner or later by unequivocal signs of chronic nephritis.

6. Do the characters of the retinitis in different cases, as has been recently asserted, justify any inference as to the kind of nephritis (chronic interstitial or chronic parenchymatous) from which the patient is suffering? Attention is here called to the importance of watching the course of the retinal disease from beginning to end, and of distinguishing between the two kinds of white opacities: the soft-edged, white, or grayish white patches in the nerve-fiber layer, and the brilliant, intensely white, sharply-defined patches composed of confluent dots situated in the deeper layers and often arranged in the familiar radiating pattern around the yellow-spot.

7. When retinitis occurs in both glycosuria and albuminuria, to which of these is it due? Retinitis in diabetic persons, whether their urine contains albumin or not, occurs later in life than albuminuric retinitis, but the relative liability of the sexes is about the same as in the ordinary albuminuric retinitis (excluding pregnancy cases).

8. Other points needing elucidation: The influence (a) of scarlet fever and (b) inherited syphilis in producing the chronic renal disease leading to retinitis; (c) the occurrence of renal retinitis in only one eye; (d) cases in which more than one attack of retinitis has been seen and watched through, with special reference to the changes left by the first attack, and to the effect of retinal atrophy on the characters of a second attack; (e) when pigment spots are left by renal retinitis, why are they so often found at the periphery of the fundus? (f) the cause of the night blindness occasionally met with in renal retinitis; (g) the nature and ophthalmoscopic appearances of the choroiditis said to occur in some cases of albuminuria; (h) the nature of the white, opaque thickening of the coats of arteries and veins seen after some cases, and of the appearances resembling retinitis pigmentosa after others.

The Management of Pregnancy Complicated by Uterine Fibroids.

DR. AMAND ROUTH, London, read a paper on this subject. After an introduction, the danger of the complication is discussed, and it shows that with modern methods the maternal mortality has been greatly diminished.

As to the effect of pregnancy on the fibroids it is doubted whether individual fibroids rapidly enlarge during pregnancy, and also whether marked atrophy usually takes place during involution. The tendency to degeneration of the fibroids, and the danger arising therefrom, especially as regards infection during the puerperium, is dwelt on, as well as the tendency of submucous fibroids to become extruded and necrotic.

In reference to the effect of fibroids on pregnancy, the view is taken that sterility is not often caused by fibroids, and if present is due to changes in the endometrium and to altered relation of tube and ovary. It is further shown that abortion is not often induced by fibroids unless they are submucous. Fetal malpresentations and placenta previa are shown to be frequent. Uterine inertia is not usual, but delay in labor is the rule. Postpartum hemorrhage is frequent. Obstruction to the birth of the child often threatens, but is almost consistently absent at labor owing to the spontaneous elevation of the pelvic fibroids during the last few weeks or days of pregnancy. Sepsis with secondary infection of the fibroids is a great danger in the puerperium.

Concerning the treatment, in all cases an expectant treatment is indicated unless there are urgent symptoms. (a) Before fetal viability, gentle attempts may be made to replace a pelvic fibroid. Induction of abortion should be abandoned. If urgent pressure symptoms supervene, myomectomy becomes the ideal operation for subserous fibroids, and failing that, hysterectomy. The indications for the two operations are discussed. (b) After fetal viability, reposition of an obstructing fibroid may be tried, leaving radical treatment for a later date. The danger to the mother of delivering a child by forceps, version, or embryotomy is insisted on. If a cervical fibroid be present it may be dealt with by vaginal enucleation as an alternative to panhysterectomy. In all other cases of obstructing fibroid, abdominal section is required, and as a first step the child must be delivered by cesarean section.

Subsequent alternative procedures are enumerated by the author as follows: 1. Cesarean section alone—this would rarely be the right treatment. 2. Sterilization of the patient by oöphorectomy, with the hope that atrophy of the fibroids would follow, would now rarely be considered a satisfactory operation. 3. Myomectomy. Sometimes this operation is indicated, but should always be preceded by cesarean section. 4. Abdominal hysterectomy. Preference is given to the supravaginal operation, with retroperitoneal treatment of the stump by Baer's or Chrobak's method, and to panhysterectomy by Doyen's method. One ovary at least, if healthy, should be retained.

Two successful cases at full term of supravaginal hysterectomy with retroperitoneal treatment of the stump were reported.

During the puerperium, if fibroids become infected from uterine sepsis, a prompt panhysterectomy, he believes, may save the patient's life.

Trypanosomiasis.

Sir Patrick Manson discussed this subject. After referring to the history of the subject and its importance, he discussed the following points:

1. *Examination of Blood for Tropical Micro-organisms.*—For an examination of the blood in the tropics, in addition to enumeration of the different kinds of blood corpuscles, three classes of micro-organisms have to be kept in view. Each of these demands its special method of preparation of the blood film and special magnifying power. The search for (a) filariæ is best conducted in thick, unfixed dehemoglobinized, anilin-dye stained films with a low magnification—½ inch to ¾ inch objective to ¾ inch objective; for (b) trypanosomes a thinnish, fixed anilin-dye stained film with an ⅛ inch to a ¼ inch objective; for (c) malaria parasites and bacteria a very thin, fixed and stained film with a 1/12 inch immersion lens.

2. *The Clinical Features of Trypanosomiasis.*—In the European (a) irregular fever, (b) fugitive patches of erythema, (c) irregularly distributed cutaneous and subcutaneous edema, (d) muscular debility, (e) rapid pulse, (f) history of painful inflamed bite. These seem to be constant. Additional but apparently not invariable or absolutely characteristic features are enlargement of the spleen, mononuclear leucocytosis and affections of the eye.

In the native, judging from some of Dutton's cases, the trypanosome may give rise to no obvious clinical symptoms.

3. *Possible Relationship to Other Diseases.*—An association with sleeping sickness has been pointed out by Castellani and confirmed by Bruce. Castellani, by indicating the frequent presence of the parasite in the cerebrospinal fluid and blood, and Bruce, by showing their invariable presence in all the considerable number of cases which he has examined at Entebbe, have adduced presumptive evidence in favor of regarding the trypanosome as the cause of this disease. Although such evidence points to such an inference, it can not be said to be conclusive. The occurrence of the parasite in the cerebrospinal fluid, that is, in close relationship with the seat of sleeping sickness—the nervous system—is a strong argument for the hypothesis; but the mere concurrence of the parasite and the disease in a limited number of cases coming from a very limited district must not be given too much weight.

He has shown for the Congo, and Low and Castellani for Entebbe, that a similar concurrence obtains in the cases of filaria perstans, but we now know that there are districts where filaria perstans is rare and sleeping sickness common, and vice versa; it is possible that when fuller investigation has been made into the distribution of the trypanosome we shall learn that a similar non-correspondence in the distribution of the latter parasite and this disease may obtain. Against a specific relationship of the trypanosome to sleeping sickness are the facts that the parasite has not given rise to the disease in Europeans, and that the parasite has not been found in sleeping sickness on the Congo or in West Africa. The former objection might be explained by the assumption suggested by Castellani that the trypanosome hitherto found in Europeans is a different species to that found in sleeping sickness; the latter objection, and it is one which is quite entertainable, might be explained by the probability that so far the blood in Congo sleeping sickness has not been critically examined for trypanosomes in a sufficient number of cases.

On the other hand, it is quite conceivable that the trypanosome of the African bears the same pathogenic relationship to the European that the trypanosome of the African wild game bears to exotic domestic animals; that is to say, that whereas the native man and beast are immune in a pathogenic sense to the native trypanosome, the exotic European and European domestic animals are not so. Such a theory seems to be more in harmony with the epidemiology, symptoms, and pathology of sleeping sickness than that enunciated by Castellani and endorsed by Bruce.

Certain obscure tropical fevers should be studied with an eye to a possible trypanosoma etiology, notably hyperpyrexial fever of West Africa and kala-azar of India and elsewhere.

Before much progress in this direction can be made, better and surer methods must be devised for determining the presence or absence of trypanosomes. We must have more easily applied microscopic methods, and, above all, we must find some easily available susceptible animal.

4. *The prognosis of trypanosomiasis* is not necessarily bad; that of sleeping sickness is always so. This is another argument against regarding sleeping sickness as a trypanosoma disease.

5. *Treatment* as yet must be conducted on general principles—rest and tonic influences.

6. *The prophylaxis* will be surely indicated so soon as we know what animal probably, judging by analogy and a small number of facts, one of the Tabanidæ is of the inoculating agent.

(*To be continued.*)

CANADIAN MEDICAL ASSOCIATION.

Thirty-sixth Annual Meeting, held at London, Ont., Aug. 25 to 28, 1903.

The President, W. H. Moorhouse, M.B., London, in the Chair.

This meeting was a very interesting and profitable one, and over 300 physicians were in attendance. A summary of some of the scientific papers follows.

Address in Medicine—The Lymph Circulation in Modern Medicine.

Dr. H. A. McCallum, F.R.C.P., delivered the address in medicine. He pointed out that the lymph circulation during the last decade has assumed enormous importance in the physiologic world. Twelve years ago Heidenhain experimented with different agents to determine their effect on the amount and character of the lymph coming from the thoracic duct; he was able to influence its quantity and quality.

From his experiments he concluded that the endothelial cells of the capillary wall acted as a secretive filter. Many physiologists from physiologic evidence have arrived at a separate conclusion that lymph depends on tissue activity; as an illustration, a limb in perfect repose gives no lymph from the lymph ducts; massage, active or passive movement, is at once followed by a free flow. The quiescent animal, it is now agreed, gives lymph from the thoracic duct, almost wholly obtained from the viscera.

In order to arrive at a clear comprehension the modern anatomy of the lymphatics should be considered. Ranvier, Sala, W. G. McCallum and Florence R. Sabine have separately agreed that the lymphatic system is a modified portion of the circulatory system; that it grew backward from the subclavian vein by the process of budding, gradually invading the tissues; that the ends of the lymphatics are blind, like the lacteals, and that they had no physical connection with the tissue spaces. Certain tissues, like cartilage and cornea, are not invaded by lymphatic capillaries.

These anatomic facts disprove all lymph circulation theories, since they prove that lymph is a double circulation composed of tissue juices and the lymphatic or absorbent circulation.

The lymphatic circulation is independent, the interchange on the part of lymph is to rid itself of offensive material and certain secretions as defensive proteids and to obtain in exchange from the blood nutritive material and oxygen.

The two great forces of lymph circulation are glandular activity and the muscular system. The great amount of the involuntary muscular tissue due to its wide area was shown to exist in the skin, modern research on the relation of the skin to internal viscera was pointed out, and the sympathetic pain reflected from the viscera could be palliated by a reflex act from the skin to the viscus; the lung reflex of Abraham was an example.

The importance of the skin as an external body connecting with all forms of impressions was pointed out, we would not

possess a heat regulating mechanism if it were not that impressions could wake up the laboratories of the body. The application of cold, heat, sunshine and fresh air are primal forces, and they act on external body world as in treatment of phthisis, the cold bath treatment of typhoid and the massage treatment of malnutrition. If the skin is so potent, how great must be the influence of the central nervous system in influencing vital activity in the way of training the patient to cease complaining to minimize sufferings and to alternate periods of alertness and absolute repose.

The importance of the lymphatic circulation in the solution of unsolved medical problems and its ancient character were pointed out. It is a field of inquiry that will be enriched in the future.

The Physiologic Generation Cycle of Woman.

DR. JENNIE G. DRENNAN, St. Thomas, Ont., said that we can see in the process of evolution that structure is determined and preceded by function and function by environment. Thus in the generative system changes due to changes in environment occur. Adaptation and heredity are the two factors which cause the changes wrought by evolution. Thus evolution works both backward and forward. The physiologic generative cycle is comprised of three factors, ovulation, pregnancy and lactation. These follow each other in physiologic sequence, one being completed before another begins. Every physiologic process is accompanied by a physiologic hyperemia, and so during the different periods the circulation is increased in that organ, which is functionally active. If from any cause a larger amount of blood is directed to a non-active organ the active organ is deprived of some of its normal blood supply and its function is lessened.

Ovulation, with its attending sexual excitement, is to the mammal what blossoming is to the plant, an evidence on the part of each that a seed is ready for impregnation. Fecundation normally should follow ovulation, then pregnancy and lactation. This is the physiologic cycle in mammals, and the primitive human female. But in the woman of civilization this cycle is interrupted by a lesser, a monthly, one, consisting of ovulation and menstruation. This is a pathologic condition arising from non-adherence to natural law. In primitive woman this lesser cycle occurs only occasionally and does not interfere with the larger circle, but as the scale of civilization is ascended the reverse is the case. Civilization precedes menstruation. Every menstruation is the sign of a disappointed pregnancy. The human female has thirteen of the periods in a year; why this frequency in an animal whose offspring requires longer time for development *in utero* and for sustenance after birth? Should one not naturally expect ovulation to occur at much longer intervals? Such would be the case if natural law had been and were now obeyed; if an adaptation to a pernicious environment had not occurred.

In mammals and primitive woman ovulation occurs at distinct periods of the year and at no other time. Mating with the primitive woman was much like that of the brute creation now; as soon as she was sexually mature she married and entered on the physiologic cycle of a mammal, one factor of this cycle following another as night follows day and day night. As she nourished her child about two years, the length of the cycle would be about three years. Primitive peoples do not produce large families.

In the married aspirant to civilization a disrespect to natural law has arisen, and error has been handed down. As a race becomes more artificial in its mode of life it becomes a more sexually-inclined race; every factor in life is then sought as a source of pleasure. The sexual element becomes adapted to the new state of life; the function of the ovary is increased and ovulation becomes a monthly phenomenon and the lesser cycle predominates.

The Size of the Pupil as an Aid to Diagnosis.

DR. J. T. DUNCAN gave this classification:

A. Pupil may have pupils evenly contracted. This may indicate: (1) locomotor ataxia, (2) meningitis and encephalitis (early stages), (3) chronic inflammation, cervical cord, (4) apoplexy of pons, (5) epileptic fits (early), (6) uremia, (7) tobacco amblyopia, (8) retinitis, (9) opium poisoning, (10) use of myotics.

B. Pupils may be evenly dilated: (1) paralysis of both third nerves (post-diphtheritic), (2) intracranial tumors (late), (3) intracranial effusions, (4) irritation cervical sympathetic, (5) acute inflammation, cervical cord, (6) premonitory of locomotor ataxia, (7) after epileptic fits, (8) cataracts, (9) amaurosis, (10) acute mania or melancholia, (11) mydriatics.

C. Pupils may be unequal, then we suspect: (1) locomotor ataxia, (2) general paralysis of insane, (3) unilateral lesion of third or sympathetic nerve, (4) pain in branch of fifth nerve, (5) old iritis, (6) carotid aneurism or tumor of neck, (7) use of a myotic or mydriatic in one eye, (8) unilateral cranial lesion, (9) acute glaucoma (unilateral).

I. The pupils are contracted and fixed: In list A we exclude uremia, meningitis and encephalitis, retinitis, tobacco amblyopia. The remaining conditions can be differentially diagnosed.

II. Pupils are evenly dilated and fixed: Rare. Present in (1) amaurosis, (2) use of mydriatics, (3) complete paralysis of both third nerves.

III. Pupils are uneven but fixed: This usually points to locomotor ataxia or general paralysis of insane.

Surgical Treatment of Hallux Valvus and Bunion.

DR. JAMES NEWELL said, in this paper, that in hallux valgus the great toe is outwardly deflected, uncovering head of first metatarsal bone, and base of phalanx is dislocated outward, resulting in tissue hypertrophy and often false bursæ. Palliative treatment is of little use; it consists in the wearing of a proper fitting shoe and keeping the great toe in position by some mechanical means.

Cases with well-marked deformity and pain require an operation. The technic must be thoroughly aseptic, not forgetting the cleansing of the skin between the toes of the patient. Incision should be made along inner side of great toe with its center over the bunion, excise the false bursa if present, deepen incision and retract the tissues, open joint and divide the ligaments. Insert a small metacarpal saw, dividing the head of the metatarsal bone just behind articular cartilage, sawing through from above, downward and backward. With bone forceps trim off sharp edges and remove exostoses. Wound is stitched with silkworm-gut sutures, a pad of cotton is placed between great and second toes, a sheet-iron splint with an upturned piece to separate great and second toes and foot and leg bandaged. Passive motion is began in third week and splint removed in four weeks. The results of the operation are ideal.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Local Anesthesia.

The following simple method of producing local anesthesia is noted in an abstract appearing in *Med. Age*, in which a solution composed of adrenalin chlorid and cocain is used in the following proportions:

℞.	Sol. adrenalin chloridi	♏ii	8 |
	Cocainæ hydrochlor.	gr. v	|30
	Aquæ	ʒss	15|

M. Sig.: Fold lint into four layers and saturate it with the foregoing solution and place it on the positive electrode of a galvanic battery. A large negative electrode should be applied elsewhere, and a current of 15 to 30 milliamperes gradually turned on and continued for 15 or 20 minutes. The surface should then be washed with ether, when superficial operations

may be performed without pain and with no loss of blood. [The strength of the adrenalin solution is not given, but either 1-1,000 or 1-5,000 may be used.]

Foisy, in *La Presse Méd.*, combines the foregoing solutions as follows:

℞. Sol. cocainæ (1-200) 3iiss 10
Sol. adrenalin chloridi (1-1,000) ....gtt. x 65

M. Sig.: To be used locally in the necessary amounts.

In opening a felon or a painful boil he employs a weak solution of cocain, probably 15 drops of a 1 per cent. solution of cocain mixed with 4 or 5 drops of adrenalin. In cases where free incision or the removal of morbid tissues is necessary, such as incision of a carbuncle or removal of suppurating lymphatics, the following is used:

℞. Sol. cocainæ (1-200) 3v-vi 20.-25
Sol. adrenalin (1-1,000) .....gtt. 10-15 65-1.00

M. Sig.: To be used locally.

Cancer.

G. Mohn, according to an abstract in *Medicine*, states that he has obtained positive results in the treatment of ulcerating epitheliomas by simple applications saturated with adrenalin. By this application the hemorrhage decreased, the pain was relieved and the general health improved. In his opinion the growths were markedly retarded in their progress for a considerable length of time. In relieving the pain produced by cancer of the stomach, Robin, in *Rev. Med. du Canada*, recommends the following combination:

℞. Cocainæ hydrochlor. .....gr. 3/4 05
Codeinæ .....gr. 3/4 05
Aquæ calcis .....ʒv 150

M. Sig.: One teaspoonful every hour until relieved.

Facial Erysipelas.

W. F. Rodue, in the *Surg. Clinic*, recommends the following combination in the treatment of facial erysipelas:

℞. Ichthyol 3ii 8
Etheris 3i 4
Collodii .....ʒv 20

M. Sig.: Apply locally with a camel's-hair brush two or three times daily.

According to the author this solution checks the spread of the disease and quickly relieves the pain. In those individuals who are asthenic he prescribes tincture of ferric chlorid internally and in suppurative cases calcium sulphid.

Darlin advocated the use of collodion, claiming that this dressing diminished the temperature of the part, and by compression interfered with septic absorption.

The following combinations are of value, according to *Merck's Archives*, in the local treatment of erysipelas:

℞. Resorcin 3i 4
Ichthyol 3ii 8
Ung. hydrarg. .....ʒi 30
Lanolini .....ʒi 30

M. Sig.: Anoint the parts freely, cover with oil silk and apply light dressing; or:

℞. Acidi picrici .....gr. x 65
Etheris q. s. to dissolve.
Aq. destil. .....ʒiii 90

M. Sig.: Paint over the affected area two or three times daily.

The following combination containing creolin and iodoform has also been prescribed with good results:

℞. Creolin 3ss 2
Iodoformi 3ii 8
Lanolini 3v 20

M. Ft. unguentum. Sig.: Apply locally with a camel's-hair brush and cover with gutta percha.

The following, containing lead and opium, is a common remedy, which acts very efficiently in some cases:

℞. Plumbi acetatis 3i 4
Tinct. opii .....ʒi 30
Aquæ q. s. ad.....Oi 480

M. Sig.: Shake the bottle, and apply on lint thoroughly saturated with the lotion.

Urticaria.

Balzer, according to the *Internat. Med. Mag.*, has found that a solution of menthol, thymol and carbolic acid is of service as a local application in the treatment of urticaria.

He either employs them in a 2 per cent. solution in alcohol or aromatic vinegar or combined as follows:

℞. Acidi thymici .....gr. xv 1
Acidi phenici .....gr. xxx 2
Alcoholis .....ʒvi 180

M. Sig.: Apply locally.

When the eruption is persistent and a prolonged treatment is required, he prescribes it in the form of an ointment. In urticaria caused by contact with insects he has found the application of ichthyol the most useful preparation. The treatment, however, must not be entirely local, but the careful regulation of the diet and attention to the digestive tract is of equal importance.

Anal Fissure.

The following outline of treatment, according to *Amer. Med.*, is recommended in the treatment of fissure of the anus:

The constipation should be combated by the administration of a teaspoonful of castor oil in the morning or a teaspoonful of the following powder in a small amount of water before retiring:

℞. Magnesiæ (calcined)
Lactose, āā 3v 20
Potass. bitartratis
Sulphuris (washed), āā.....3iiss 10

M. Sig.: One teaspoonful at bedtime in a little water.

At 11 o'clock in the morning an enema of linseed water or hot marshmallow water may be given. When the pains are less severe, these may be substituted by an enema of a decoction of krameria (20 parts to 1,000).

The following combinations should be used as ointments locally:

℞. Ext. krameriæ .....gr. xxx 2
Ext. opii .....gr. viiss 50
Cocainæ hydrochlor. .....gr. xii 75
Ung. populi .....ʒi 30

M. Ft. unguentum. Sig.: Apply locally night and morning; or:

℞. Ext. belladonnæ .....gr. xv 1
Plumbi acetatis (neutral) .....gr. xlv 3
Adipis .....ʒi 30

M. Ft. unguentum. Sig.: Apply locally. The following suppositories may be used as a substitute for either of the above:

℞. Iodoformi .....gr. ii 12
Ext. opii .....gr. 1/3 02
Ext. belladonnæ .....gr. 1/6 01
Ol. theobromæ.....gr. xlv 3

M. Ft. suppos. No. i. Sig.: One may be used at night and another in the morning if necessary. Forced dilatation should be practiced and locally cauterization with the silver nitrate stick every few days.

Medicolegal.

Simulation as to Pain Subject for Expert Testimony.—The Court of Civil Appeals of Texas says that, in the personal injury case of McGrew vs. the St. Louis, San Francisco & Texas Railway Company, where the party suing had been thrown from a buggy in consequence of the frightening of a horse which she was driving, that there was much evidence in the record to the effect that she was not injured to the extent claimed, and that some of her pretended injuries were feigned and simulated. One of the attending physicians who examined her injuries, and treated her for the same, testified that he had employed certain tests to ascertain whether she could feel pain in her limbs. Then he was asked whether or not she was simulating the absence of pain when the tests were applied. The court holds that it was error not to admit this evidence, the question asked, and the proposed answer

thereto, being, in its opinion, the subject of expert testimony —a matter peculiarly within the province of the physician.

A Profession is Property—Regulation of Practice.—The Supreme Court of New Jersey holds, in State vs. Chapman, that a calling, business, or profession chosen and followed is property. The legislature can not destroy it by statute without providing for compensation, any more than it can authorize the taking of real estate for a public use except on compensation. But it is within the power of the state to place reasonable regulations on the business or calling of any person. The laws regulating dentistry are of later enactment than those regulating the practice of medicine, but the principles underlying their legality are the same. And it is within the power of the state, under the police power, to impose by statute reasonable restrictions as to registration and the obtaining of a certificate of authority to engage in the practice of dentistry, and to make it a misdemeanor for a person to practice without first obtaining such certificate. The New Jersey act of March 17, 1898, entitled "An act to regulate the practice of dentistry in the state of New Jersey, and to repeal certain acts now relating to the same," is not an act taking or destroying property, but is a reasonable regulation of the practice of dentistry in that state. The act does not impair vested rights, nor is it in its criminal provisions an *ex post facto* law.

Power of President and Manager to Employ Physician.—The Court of Civil Appeals at Kansas City, Mo., holds, in the case of Evans vs. the Marion Mining Company, that the company's president and general manager had authority to bind it for medical services rendered by a physician in attending one of its employes, hurt in the course of his work through the negligence of the company. The contrary contention, it holds, was not supported by the cases cited therefor, it not appearing in them that the injury happened through the negligence of the company sought to be held liable, while, on the other hand, the officers representing the companies were of much inferior grade to that of president and general manager. In this case, it says, it must be assumed that the employe was injured through the negligence of the company. It was, therefore, liable to him for the damage occasioned by the injury, including the expense of a physician. It was directly interested in seeing that such injuries were not made worse by lack of medical attention, and that the suffering and other ill consequences should be lessened in every proper way. Its president and general manager, who was necessarily in charge of its general interests and welfare, was certainly not acting outside his duties when he was doing that which was lessening the damages for which he found it had become liable.

Duty of Railroad in Selecting Physician—Evidence.—In the case of Poling vs. the San Antonio & Aransas Pass Railway Company, where it was sought to recover damages for the loss of sight of an eye, alleged to have been occasioned by the negligence of the company in the selection of the physician who treated the case, the Court of Civil Appeals of Texas holds that there was no error in excluding evidence offered by the party suing to prove that the physician never stood an examination for license to practice medicine in Texas. It says that as to whether the physician stood an examination before the board of medical examiners that issued him a certificate authorizing him to practice medicine was immaterial to any issue in the case. The certificate was issued to him, and as to whether the board acted irregularly in its issuance could not be made a subject of inquiry in this case. Nor can the court perceive on what principle it could be contended that a publication in a local newspaper of the proceedings of the medical board of examiners of that judicial district could be admitted in evidence in this case, such publication being purely hearsay, and there being no evidence introduced or offered tending to show that the company had any knowledge of it, either at the time or after it employed this physician. Taking up the instructions given the jury, the court finds no error in telling them that, all of the evidence showing that the company derived no profit from the retention of the 50 cents per month hospital fund from each of its employes, neither had it designed same for profit, the only measure of duty owing to the party suing, an employe, by the company, arising from its agreement to furnish him with medical attention when needed, was the use of ordinary care to select, employ, and retain a competent physician as its local physician for the treatment of the party suing and its other employes in cases of sickness or injury. If they believed that the company selected, employed and retained this physician as its physician at that place, and that in selecting, employing and retaining him it used ordinary care—that is, the care that an ordinarily prudent person would have used—to select a competent physician they would find a verdict for the company, whether the physician treated the eye of the party suing properly or not.

Physician Immediately, Continuously, Wholly Disabled.—In the case of Brendon vs. the Traders' and Travelers' Accident Company of New York, it appeared that the party suing, a physician, while obliged to stand in a crowded street car, and while holding on to a strap, was, by the car starting suddenly to go around a curve, swung violently around, his weight resting on his left foot, which was held in place by the feet of other people, and his knee was twisted and strained. He felt quite a little pain at the time and a few blocks further on he transferred to another car and went to his home. The knee continued quite painful, and commenced to swell that evening. He put on cold applications and remained at home. This was the 18th of the month. In the morning the pain and swelling continued, but he made a necessary visit to a patient near by, and then returned home, and there remained. The next day the knee was still more swollen and painful, and he could scarcely move it at all. On the 21st its condition was such that he was obliged to go to bed and have it treated. A physician was called, and the knee was put in splints, and kept immovable and bandaged. He remained in bed for nearly three weeks. The First Appellate Division of the Supreme Court of New York holds that the accident "immediately, continuously and wholly disabled" him from performing any and every kind of business pertaining to his occupation, within the fair intent and meaning of an insurance policy. It says that the fact that his sense of his professional obligation to his patient led him to make a visit when he was in a crippled and substantially disabled condition was not sufficient, in and of itself, to show that he was not continuously and wholly disabled. The injury had been sustained. It affected him immediately. The disability attached immediately, and was progressive and continuous. If the insurance did not cover such a condition, it was of little value; and to allow an insurance company to receive large premiums and escape liability in these circumstances would be to sanction the perpetration of a fraud on its policy holders. His failure to make any claim for the first three days, in that he claimed for total disability for three weeks from the 21st only, may have been a waiver of the insurance for that time, and it was some evidence to be considered by the jury on the question of whether his disability was immediate; but he was not estopped thereby from claiming immediate, continuous and total disability, in order to recover the insurance for the period for which he had presented a claim, which was more favorable to the insurance company than the facts warranted.

8 Strangulated Oblique Inguinal Hernia in a Child Eleven Days Old; Operation. J. Hutchings White.

1. **Splenomedullary Leukemia Cured by Roentgen Ray.**—Senn states that he has seen many cases of the different varieties of leukemia, but the case which he describes in detail is the only one that has recovered. He attributes this exceptional result entirely to the prolonged use of the *x*-ray. He adds that he has so far not seen a single case of either carcinoma or sarcoma benefited by Roentgen treatment, but the curative power of the *x*-ray in pseudo-leukemia and genuine leukemia promises to accomplish what heretofore has not been obtained by any kind of medication. It seems to prove that, etiologically at least, both conditions are analogous, or at any rate closely allied. The case described was that of a foreign-born Jewess, 29 years of age, with typical splenomedullary leukemia, rebellious to all measures. The case appeared hopeless when, as a last resort, the *x*-ray treatment was commenced, Feb. 3, 1903, about three weeks after her admission to the hospital. The spleen, the lower end of the sternum, and the epiphyseal extremities of the long bones were exposed to the action of the rays daily for from ten to twenty minutes. During the course of the treatment the use of the *x*-ray had to be suspended for a day or two on several occasions owing to a high temperature and other symptoms of intoxication. The constitutional symptoms became very prominent at the time the spleen first presented indications of progressive decrease in its size, about three weeks after the beginning of the treatment. The blood examinations were repeated at intervals of a few days, and it was noticed that improvement kept pace with the reduction in the volume of the spleen. The first decided changes observed were the gradual disappearance of the myelocytes and eosinophiles, and the return of the erythrocytes to their normal shape. Examination of the blood made April 12 showed no myelocytes, and only a very few eosinophiles and very little poikilocytosis. March 12 the patient left the hospital, but was treated daily in the outdoor department. The spleen was so enlarged at first that it simulated a pregnancy at term, but retrogressed to its normal outlines as he shows in a photograph of the patient. He adds that there can be no longer any doubt in regard to the microbic origin of leukemia or to the anti-microbic action of the Roentgen ray. The transillumination of the affected bones undoubtedly accomplished its share in destroying the microbes of the general infective process, as the pain and tenderness disappeared entirely, as well as the occipital headache, during the early part of the treatment. He believes that the microbes of the splenomedullary leukemia are very susceptible to the destructive action of the *x*-ray, as the response to this treatment is very prompt and often violent, followed by a speedy return to normal of the spleen, medullary tissue, and the histologic constituents of the blood.

2. **Management of Pulmonary Tuberculosis in the Dispensary.**—Miller outlines the measures in vogue at the Vanderbilt Clinic, New York, to treat the tuberculous who are unable to go to a sanatorium. Two weeks of absolute rest are enforced, and if there is fever, this rest should be strictly in bed. When they resume work they are instructed to avoid all unnecessary exertion or exercise, to rest at odd moments whenever possible, and to rest absolutely after working hours. The occupation is changed if necessary. When a determined effort is made it is often possible to effect a very fair "rest cure" even while a patient is in active occupation, and perhaps supporting a family. Milk and raw eggs are the main reliance for superalimentation. He gradually accustoms his patients to the ingestion of two or three quarts of milk and from six to ten raw eggs every day, in addition to a regular diet of simple food. The increased expense of such a diet is borne by the patients or by the Charity Organization Society. In medication he prefers to err, if at all, by too little medication rather than by too much. These measures are supplemented by inspection and regulation of the homes, for which the services of a regularly trained nurse are the main reliance. She visits, makes her report, instructs the family and calls the attention of some charitable society to its needs if required. In 35 cases treated on these principles, 22 patients have increased in weight an average of four pounds to a maximum of twelve pounds; 7 of the 22 were early cases, 5 were moderately advanced, and 10 were advanced cases.

4. **Purpura Hemorrhagica Fulminans.**—MacAdam reports what he calls the first case on record of purpura hemorrhagica treated with adrenal gland preparation. The patient was a child of five. In half an hour after the purpura was recognized the child was almost moribund and had vomited several pints of blood. The case looked hopeless. Twenty drops of adrenalin solution were administered internally in a tablespoonful of water. At the end of fifteen minutes the child regained consciousness. A little color appeared in the cheeks and the pulse was perceptible at the wrist. Ten drops of adrenalin were then given and the patient continued to show evidences of improvement. For three days she received ten minims of adrenalin every three hours in orange-juice, no nourishment being permitted. At the present writing, he adds, she eats and sleeps well, apparently none the worse for her narrow escape, and but for a slight anemia, is as well as ever.

5. **The Lake Forest Scarlet-Fever Epidemic.**—Haven states that there were only 2 deaths in the 108 cases reported. The sore throats, which he considered the manifestation of scarlet fever in immunes, were the most prolific source of the spread of the contagion, also the fact that many of the cases were exceedingly mild. Fully one-third of all the cases were young adults, over 15 years old, and no age up to 40 seemed exempt. A house-to-house inspection was instituted. Every case was promptly isolated and the patient not allowed to regain his liberty until all desquamation had ceased, after which the place was fumigated by formaldehyd gas and steam and the disinfector empowered to burn mattresses and whatever else he deemed wise to destroy. A temporary auxiliary hospital was organized for scarlet fever and the hospital ambulance was fumigated each time it was used. No children were allowed on the streets, all visiting and public gatherings were positively forbidden, and special police sworn in to see that all regulations were obeyed. The epidemic vanished more quickly than it appeared, after lasting about ten weeks.

6. **The McGraw Elastic Ligature.**—Walker's conclusions in regard to this elastic ligature, given in The Journal, xl, p. 166, with five cuts, are confirmed by Kakels' experimental research on a number of dogs. He found it the quickest of all known methods of anastomosis, and states there is no loss of blood except the slight amount produced by the Lembert sutures on the serous surfaces. It is as simple as, if not simpler than the Murphy button, and there is absolutely no escape of intestinal contents, and therefore no exposure to infection of the peritoneum from this source. There is no shock, on account of short exposure and little handling of viscera, and very few lesions are made. There seems to be a uniform coaptation of peritoneal surfaces of the entire circumference of the approximated ends. The bowel seems to have been cut through without sloughing. McGraw states that three or four days is sufficient time to provide for a free opening, but his experience does not confirm this. The cutting through was only partial in 2 dogs killed the third and fourth day after entero-enterostomy, while in 3 gastroenterostomies there was only commencing severance the fifth day. The failure to cut through he attributes to too thin a ligature and to the greater thickness of the dog's stomach and intestine than that of man. For man it would be safer to use a ligature of 3 or 4 mm. thickness, and we should not hesitate to take more than an inch and a half of tissue in the ligature (especially in gastroenterostomies), as the more tissue and the thicker the ligature, the more pressure will be brought to bear and the quicker it will cut through. Barring the disadvantages caused by its slow action in cutting through, he qualifies this ligature as superior to all other methods of intestinal approximation.

9. **Cardioptosis.**—Abrams reviews his experience with voluntary cardioptosis, cardioptosis associated with ptoses of the abdominal viscera, the cardioptosis of accommodation, and primary essential cardioptosis. He says of the latter:

It may often be present without subjective symptoms. In other instances a feeling of weight or oppression is experienced in the lower chest which is referred by the patient to the lower sternal region or epigastrium associated with epigastric pulsation and dyspnea. The latter is intensified by exertion. The upper portion of cardiac dulness, superficial and deep, will be found to be lower than normal. The apex beat is with difficulty palpated and, in lieu of the punctated beat, a diffuse one is felt. Auscultation may or may not elicit cardiac murmurs and, if present, they are greatly influenced by posture—a certain posture will bring them in evidence, whereas another posture will cause their evanescence. The murmurs are probably accidental and dependent on the malposition of the heart. The pulse suggests diminished tension of the arterial wall; it is soft, readily compressible and its dicrotic character is clearly brought out in the sphygmogram. The pathognomonic signs of cardioptosis are elicited by skiascopy. The long axis of the heart appears to be practically parallel with the surface of the diaphragm; the boundaries are poorly defined and deep inspiration does not bring into evidence the clearly-defined space between the heart and the diaphragm. This posture of the heart could be assumed if the midriff were abnormally high, as in abdominal distension, yet, if the long axis of the heart were measured, it would be found by describing the distance of the axis on the chest wall, that it would extend higher in the thorax than would a normal heart. The highest anatomic point of the heart is represented by the left auricle, which is at the lower border of the sternal insertion of the second rib, its lowest point is at the upper border of the sixth costal cartilage or in the fifth intercostal space just within the mammary line. Measurement of the long axis of the heart in cardioptosis would show that the heart lies lower than normal. The site of the normal heart is influenced by respiration and attitude. In cardioptosis there is little or no respiratory or attitudinal dislocation.

Treatment is limited to the wearing of a good fitting abdominal support with pressure exerted in the upper abdomen. In cardioptosis associated with Glénard's disease, exercises having for their object strengthening of the abdominal muscles and the diaphragm often yield excellent results associated with massage, faradization and hydrotherapeutic procedures. He has seen no benefit from medication.

11. **Yellow Glass in Examination and Treatment of Eyes.**—Seabrook relates tests with photochromotherapy of the eye, having found that there was less congestion, lacrimation, photobia and pain in examined eyes, when an amber yellow glass lens was used than without it. Vision is not impaired by the yellow glass, chromatic aberration of the eye is corrected by it, and dazzling reflections are softened and modified. The sphincter of the iris is not contracted so much by yellow as white light. The indications for the use of yellow glasses in the treatment of asthenopia and ocular neuralgias are easy to determine. The most beneficial results might perhaps be expected in that class of cases having diminished vision and hyperesthesia of the retina, and he reports three such cases confirming this assumption. His experience with these and other ocular affections shows conclusively that amber yellow glass has certain advantages for the ophthalmologist and good effects on the internal structure of the eye in certain conditions. He uses in examinations a bi-convex lens of white glass split and cemented on a plain glass of medium light amber yellow. For patients he orders amber yellow glasses. He had no experience of their use in "summer conjunctivitis" when he wrote, but believes they will prove particularly soothing in this case, protecting against irritation and improving vision.

12. **Treatment of Chronic Catarrhal Deafness.**—Among other constitutional causes of this condition Hopkins mentions that disordered digestion aggravates and perpetuates a large proportion of cases. Gout is another factor sometimes overlooked, as also typhoid fever. He has lately been experimenting with an electric douche applied to the entire intra-tympanic cavity. The promptness with which relief follows this electrolytic-cataphoric application is sometimes remarkable. He found iodin cataphoresis a valuable adjuvant in certain selected cases, the auditory canal being filled with iodin solution and a cataphoric electrode applied, anode direct to the tympanum. His experience with superheated air has also been favorable. Scores of cases which had obstinately resisted every other form of treatment slowly, but gradually, retrogressed under the application of superheated air to the tympanum until marked improvement in hearing and relief of tinnitus resulted. He believes that the superheated compressed-air treatment, when indicated and judiciously employed, in conjunction with such other measures as may be indicated, will give results which would be utterly unattainable without its aid.

13. **Clinical Value of Blood Pressure.**—Richardson describes the instrument introduced by Hill and Bernard, proclaiming that it is exact and eliminates the personal equation in observation. It consists of a rubber bag connected with a dial graduated in mm. Hg. The bag is securely and tightly fastened around the arm or leg of the patient, and air pumped into the bag till the pressure is sufficient to close the artery; the point of closure being indicated by the cessation of the oscillations of the needle of the aneroid. To obtain the mean pressure, the air is allowed to escape from the bag until the maximum oscillation of the needle occurs, at which point the pressure in the artery and in the bag are the same. It requires very little practice to become familiar with the instrument. There are two pressures in the arterial system which can be estimated by this instrument, viz., the maximum or force of the systole and the mean or the pressure in the artery. As the arteries collapse if empty, it is evident that the force required to obliterate them when full will represent the force of the blood driven into them by the heart. He calls attention to the high mean blood pressure as an important early, diagnostic sign of Bright's disease. It may be determined even before the apex beat has moved to the left. He describes the variations in the blood pressure induced by different affections, as he determined them with this instrument, claiming that from the clinical standpoint, the observation of the maximum and minimum blood-pressures and their relation to one another is of immense advantage, not only as an indication for treatment but also as a measurement of progress.

14. **Care of the Umbilical Cord.**—Harden uses tape and has never seen hemorrhage or laceration of the cord in 500 cases in which it was tied with tape. In 35 cases in which silk was used, he noted 5 cases of laceration and 5 of hemorrhage. After cleansing the region he draws over the cord a piece of sterile gauze, 4x4 inches doubled, with a small slit in the center. He pulls the cord through this by the strings of the ligature and pushes the gauze down on the abdomen, then draws it up over the cord and cuts the ends of the tape. This plain dry dressing can be left untouched until the cord falls off, and does not offer a culture medium for germs as when salves, etc., are used.

16. **Other Causes than Syphilis for Paresis.**—Sights argues that the prevailing cause of paresis is an overworked mind centralizing the mental energies without relaxation, whether in worry over financial troubles or over syphilitic infection or a concentration of the mental forces in any single avenue of life. Mental worry and nervous strain precipitate the disease in susceptible individuals, especially in those who are sensitive, with an inherited pessimistic tendency.

17 Memorial Meeting to Morrill Wyman. Henry P. Walcott and others.
18 *The Surgical Treatment of Gastric Ulcer. John C. Munro.
19 *The Medical Treatment of Gastric Ulcer. Hubert G. Wilbur.

18. **Treatment of Gastric Ulcer.**—Munro pleads for the more intimate association of the internist and the surgeon in the study of gastric ulcer. The physician does not yet fully appreciate that an operation performed on the average patient with a mortality so small that it may practically be disregarded, becomes serious or even unjustifiable if done in the presence of persistent hemorrhage, prolonged sepsis, starvation,

absorption of ptomains, etc. To determine whether there is a condition amenable to medical treatment the physician must experiment to a certain extent. If he succeeds, well and good; if he fails, he must be willing to seek the co-operation of the surgeon, or better, he should have sought it early in order that both should study the case and both should learn, each from the other's findings. The following types he regards as best considered as surgical: probable cases of relapsing acute hemorrhage; cases with hemorrhage if persistent and causing anemia; perforation; recurrent ulcer, pure and simple, attended with dyspepsia and starvation; pyloric obstruction; adhesions following ulcer or independent of it; scar contraction of the body of the stomach, and some cases of intractable dyspepsia, perhaps originating in an ulcer, and for which no definite pathology is known.

19. **Medical Treatment of Gastric Ulcer.**—Wilbur refers in the course of this article to the tendency of anemia to induce gastric ulcer. Experiments on animals have shown that gastric ulcer develops from much slighter irritation and heals more slowly when the animals have been rendered anemic than when the blood is in its normal condition. In chlorotic females it would be wise to regulate the diet to avoid very hot things, coarse foods, highly acid and highly seasoned foods, also avoid corsets and tight clothing. Occupation may have its effect in the causation of ulcer. Seamstresses, typewriters, tailors and clerks, who lean against a machine or desk, are all liable to ulcers. In case of perforation, surgical interference is at once demanded. If the surgeon is not at hand, give morphia subcutaneously to quiet peristalsis and relieve pain, and brandy and coffee by enema to sustain the heart. Hemorrhage occurs in about half the cases. In repeated and profuse hemorrhage Dreschfeld advises turpentine. He gives it in capsules or in emulsion. He cites several cases of hematemesis rebellious to the usual measures, the patients pulseless and blanched, in which the first dose of turpentine arrested the hemorrhage. It is well borne by the stomach.

24 *Etiology of Dysmenorrhea. J. Thompson Schell.
25 *A Successful Treatment for Morphinism, with Report of Case. J. Ben. Jones.

20. **Enterostomy for Drainage and Nourishment.**—After the loop of bowel is brought out and opened, a rectal tube is inserted first in one direction and then in the other, for several feet each way. This allows escape of gas and feces with less risk of soiling the peritoneum than by other methods. The special indications for enterostomy considered in the article are: 1, temporary drainage of a distended intestine, allowing it to regain its normal tone in cases of functional paralysis of the bowel of septic or other origin, especially in those cases following appendicitis with peritonitis. 2. To enable one to nourish a patient whose stomach and rectum are for any reason irritable and unable to retain or absorb a sufficient amount of nourishment. The operation of enterostomy, when quickly done under local anesthesia, is a comparatively slight one and causes little disturbance to the patient. The relief afforded thereby often enables him to withstand, later, more radical measures. The amount of fluid that can be given in twenty-four hours by this means and retained is surprisingly large. Finney calls attention not only to the advantages of relieving the distended intestine, but insists that the intestinal fistula once established should be looked on more as a mouth than as an anus. It should be used for irrigation of the intestinal canal, for the nourishment of the patient and for the introduction of cathartics. He has often noticed that food introduced into the intestinal canal through the fistula had of itself a stimulating effect on peristalsis. He reports seven cases in detail, some followed by postmortem examination, as the enterostomy was undertaken as a last resort. It always caused great relief and postponed the inevitable fatal termination, and saved several otherwise doomed patients. The fistula usually closes spontaneously.

21. **Enteroptosis.**—Brown describes in this part of his article the symptoms of enteroptosis in general. He says:

> There may be absolutely no symptoms associated with the condition on the one hand, and this is especially so in the acquired cases, while on the other hand we may have symptoms of the most aggravated type of neurasthenia, to which are added various abdominal symptoms due to displacement of the various viscera, such as indigestion, constipation, pain in various portions of the abdomen, a feeling of a lack of abdominal support and many other symptoms.
>
> Among the more important objective symptoms may be mentioned a flattened abdomen, or one flattened in the epigastric region and distended below the level of the umbilicus, sensitiveness to pressure near the tenth rib, a cord-like transverse colon, through which the pulsation of the aorta can be distinctly felt, while in all cases a careful examination of the abdomen reveals the displacement of several of the viscera. Some authors insist that pain and fatigue in the early afternoon and in the very early hours of the morning are important, because these hours correspond in general to periods of duodenal digestion, while in the severe cases many describe marked nervous crises, hysteria, insomnia and despondency.

He discusses the frequency, etiology, symptomatology, treatment and prognosis of enteroptosis, gastroptosis, nephroptosis and hepatoptosis, quoting extensively from international literature.

22. **Course of Diseases During Pregnancy.**—Castelli concludes his paper from the number of March 28, studying diseases of the respiratory apparatus during pregnancy and also diseases of the liver and kidneys. He states that the physician must bear in mind that there is a diminution of hemoglobin in the blood during pregnancy, and with this diminution there is a corresponding lessening of oxidation or respiratory power of the blood and an increase in the carbonic acid discharged by the lungs. In chronic nephritis the death of the child from placental changes is so common that consideration for the life of the child must be always subsidiary to the interests of the mother. He believes that the danger to the mother increases and the hope of giving birth to a living child diminishes, the earlier the lesion of the kidney manifests itself in pregnancy. If nephritis is shown in the earlier period of pregnancy, the chances of recovery and of a living child are problematic, while if the pregnancy is stopped in time, the recovery of the mother is certain. He advises intervention between the fifth and sixth months. Waiting, while of no advantage to the fetus, may prove a great danger to the mother. In regard to tuberculosis he remarks that athrepsia, as a rule, is produced by the tuberculous mother, whose infection was not sufficient to kill the fetus in intrauterine life.

23. **Typhoid Perforation.**—Voorsanger lays stress on the white blood count in the diagnosis of typhoid, attaching as much, if not more, importance to it than to the Widal reaction. The leukopenia occurs during the first few days, and is always very positive, being, as a general rule, between 3,000 and 5,000. A rise always means a complication. In the case of perforation described the only symptoms were the dropping temperature, the high pulse and tympanites.

24. **Etiology of Dysmenorrhea.**—Schell emphasizes that the origin of dysmenorrhea may be local or pelvic, general or constitutional, or merely reflex, or it may be due to a combination of two or more of these causes.

25. **Hyoscin Treatment of Morphinism.**—Jones reports the particulars of a case treated with wonderful success according to the method advocated by Dr. Geo. E. Pettey. His principle is that morphinism is due to autotoxemia, and the chief cause of the phenomena known as withdrawal symptoms is the presence of this toxic matter in the system and not the drug itself. When the system is cleansed of the accumulated effete material, autotoxemia overcome, and the portal system disengorged, morphin can be at once withdrawn without shock, collapse, or danger to life, and the suffering subsides in a few days. He gives purgatives, hyoscin and strychnin and sodium hyposulphite. Jones also witnessed ten other patients thus treated. There was no appearance of collapse, heart failure or other untoward symptom in any case, and there was an entire absence of the nervous symptoms usually encountered. The patients slept almost normally from the very beginning of

treatment. The details of Pettey's method were published in THE JOURNAL recently, xl, p. 1757.

26 *Relation of the Anesthetist to the Patient and to the Surgeon; with Some Interesting Experiences, on which This Paper is Partly Based. S. Ormond Goldan.
27 *The Iodin Treatment of Puerperal Sepsis. W. R. Pryor.
28 *The Treatment of Papilloma of the Larynx in Children. J. E. Summers, Jr.
29 Regicides; Sane and Insane. (Continued.) E. C. Spitzka.
30 The Treatment of the Summer Diarrhea of Children. W. C. Rucker.

26. **Relation of Anesthetist to the Patient and to the Surgeon.**—Goldan pleads for complete equality ethically, professionally, materially, between the anesthetist and the surgeon. Many surgeons, he thinks, lose sight of the fact that the anesthetist, both by education and training, is their professional equal, and he relates a number of incidents from his own experience which show the abuses that still prevail in many quarters. The only right for their existence is usage and the non-assertion of the anesthetist. Through the ignorance of the patient and many years of bad custom the surgeon assumes charge of the entire operation instead of informing the patient that he operates and others anesthetize. The anesthetist owes it to the patient and to himself that he should examine the patient before the operation. He is liable to discover valuable points in regard to the anesthesia by this examination, and the relation of the anesthetist to the patient being thus direct, he receives what he is justly entitled to and no more—the full credit for his own work and a fee accordingly. The highest medical standard, he argues, allows that the medical man is entitled to a maximum fee in every case treated. In many instances this would be a burden to the patient and, knowing this, the practitioner follows the beneficent plan of charging in keeping with the financial circumstances of his patient. In a word, he does not overcharge the rich, but he undercharges the poor. The operator, in case of a particularly important patient, labors under a greater responsibility, and he charges accordingly. The same should, and must, obtain with the anesthetist, and the signs indicate, Goldan believes, that this equality between the two is becoming recognized. In his experience the patients do not object to remunerating the anesthetist directly. When requested to send in his account to the operator he does so only as a matter of courtesy, and sees no reason why the charge should be less than if sent directly to the patient.

27. **Iodin Treatment of Puerperal Sepsis.**—Pryor found streptococci in the uterine cavity in 36 out of 37 cases examined and in the entire number these cocci were found in the serum, lymph or free pus in the posterior cul-de-sac. He is convinced that this corroborates his assumption that puerperal sepsis is the result of a streptococcic puerperal septic lymphangitis. Treatment should be along the lines of sterilization of the original lesions, and inducing absorption by the infected lymphatics of some potent, harmless antiseptic, supplemented by measures to promote the eliminative functions. He used to curette the infected uterus and open up the cul-de-sac, concluding by packing them both with an abundance of iodoform gauze "in order to drain away something." He found, however, that there was nothing to drain away except serum, and yet the cases recovered beautifully. He had builded better than he knew, and later researches have demonstrated that the fine results attained were due to absorption from the gauze. The iodoform gives up its iodin, partly in obedience to the influence of heat and partly from the chemical action of the blood serum. Local iodism is produced, and this sterilizes the pelvis, while the iodin absorbed by the lymphatics appears in the urine in an average of five hours, sometimes as early as two, showing that it has a systemic effect as well. He accompanies this massive gauze packing with saline per rectum or intravenously to facilitate the elimination of the iodin and of toxins by the kidneys. He has thus treated 37 cases; 27 had not previously been operated on, and only 1 died, while 10 had been curetted before coming into his hands and 3 died. He is now engaged on research to determine whether this local and general iodin sterilization may not be obtained through the infected lymphatics in some still simpler manner.

28. **Treatment of Papilloma of Larynx in Children.**—Summers lauds tracheotomy as the most available remedy for this condition. Intubation is a failure and the justifiability of laryngotomy is questionable. The general practitioner, he thinks, can make the diagnosis and the services of a specialist are not required.

33 Eye Strain from the Standpoint of the Neurologist. Philip Zenner.
34 Surgery of Prostate, Pancreas, Diaphragm, Spleen and Thyroid. (Continued.) B. Merrill Ricketts.

31. **Eye Strain and Its Results.**—Ayres relates several pointed illustrations showing the physical effects possible from eye strain. One patient, a lad of 15, suffered invariably from nausea in a crowded room or on attempting to study. Another, a child of 6, suffered daily from nausea, which came on while playing and subsided when he reposed. As he did not use his eyes for reading, the influence of school life was not a factor. In another case severe choreic symptoms entirely disappeared under correction. A fourth patient was a woman of 33 who had suffered from nausea, headache and dyspepsia and had been treated for stomach trouble for five years. The relief by the adjustment of glasses was immediate and permanent. All the patients were cured of these symptoms by proper correction. Decided improvement was likewise obtained in a child of 7 presenting ametropia, muscular unbalance, nervousness and mild choreic symptoms.

43 Pneumonia. Victor I. Miller.

36. **Bullet Wounds.**—From a study of modern high velocity military bullets, Law advises to refrain from meddlesome treatment of the wounds. Dressings should be less frequently changed on the field for fear of infection. He also notices the peculiar lack of susceptibility of the blood vessels to wounds, and the rarity of external primary hemorrhage. Lodgment of the projectile is relatively frequent, on account of the range of fire, but attempts at removal should be abstained from unless it causes trouble. Primary amputations are rarely necessary except with shell wounds or great infection. Fracture cases do as well as those in civil practice. Infection from the undeformed bullet is rare. Head wounds are among the most fatal class of cases and require most frequently operative interference. Joint wounds are among the most favorable class, and generally leave perfect function. Thoracic wounds, unless immediately fatal, recover with few complications. Tetanus and gangrene are exceptional. Abdominal perforating wounds constitute the most serious class and should not be operated on. He considers the high velocity steel-jacketed projectile as a step towards the end of all wars. It disables the enemy with the minimum of death, suffering and maiming, and impairs the subject less for future life after his return home.

44. **Chronic Cyanosis with Polycythemia and Enlarged Spleen.**—Osler describes a group of cases which has been elsewhere noticed by him as a new clinical entity. (See editorial, THE JOURNAL, May 23, 1903, page 1442.) He reports several other cases from the literature, and gives them a thorough analysis. He says with our imperfect knowledge of the physiology of polycythemia it would be premature to discuss at any length the pathology of this remarkable group of cases. What is needed is:

1. A careful study of all forms of chronic cyanosis with polycythemia, particularly those associated with heart disease and emphysema. (It is to be noted that the cases here reported have the highest blood count on record, much higher than the average in congenital heart disease or in dwellers at great altitudes.) 2. A more accurate study of the blood in this class of cases—the volume, the viscosity, the state of the plasma and the serum, the amount of hemoglobin, the specific gravity, and the diameter of the corpuscles. As increased viscosity of the blood, with resulting difficulty of flow, seems the most plausible explanation of cyanosis, it is especially important to test the viscosity by accurate physical methods and to determine the relation of the number of corpuscles to the viscosity of the blood. 3. The relation of the splenomegaly to the cyanosis and polyglobulism should be carefully observed. It man not be anything more than the effect of the chronic passive congestion. Future investigations will determine whether we have here in reality a new disease. The clinical picture is certainly very distinctive: the symptoms, however, are somewhat indefinite and the pathology quite obscure.

45. **Cytolysins, Autolysins, Etc.**—Flexner's article discusses the properties of blood serum, the study of agglutination, its relation to thrombosis, the presence of a special substance in certain venoms and poisons, such as some snake venoms and ricin, for which he proposes the name of "hemorrhagin" and looks on it as a cytolysin for endothelial cells and blood vessels. He refers to experiments by Noguchi and himself in modifying viper venom to remove the locally destructive effect and still leave the hemorrhagic principle by which immunity may be established. He next takes up the cytotoxins of blood serum, discussing them at length and also the autolysis of the organism, which he believes should be largely credited to the leucocytes.

46. **Alcoholic Amblyopia.**—Seven cases are reported by de Schweinitz and Edsall, which seem to them to point to the probability of the correctness of Horner's view that the amblyopia is due to toxemia set up by gastric indigestion and metabolism.

48. **Bacteriology of the Blood.**—After a review of the literature and a report of personal observations, Rosenberger says that bacteriologic examinations of the blood in the living may afford valuable information for diagnosis and intelligent treatment. This is particularly true in cases where antitoxic and bacteriologic sera are indicated. Special care as to technic is a pre-requisite; special media should be used in certain cases, as in gonococcal infection, etc. Postmortem examination of the blood should not be relied on to determine the nature of the infection as the results are often misleading and untrustworthy. In enteric fever in 535 cases the typhoid bacillus was shown to be present in the blood in over 80 per cent. Schottmüller's plea that all cases of enteric fever should be regarded as bacteriemias seems justifiable, as observers agree that bacteria can be found in the blood before a positive Widal reaction. This fact would seem to place this procedure as a diagnostic method in advance of the other and also seems to prove that the disease is often, if not always, a blood infection. He also considers that proper identification of the bacteria present in septic processes would reconcile discordant views as to the therapeutic efficacy of the antistreptococcic sera. He thinks there is also a possible future for bacteriologic examination of the blood as an aid in the diagnosis of tuberculosis and syphilis.

49. **Sublingual Growths in Infants.**—The first case apparently reported in an American in this country is detailed by Amberg, who discusses the condition, which has been observed in Southern Italy under the name of Riga's disease. The growth under the tongue is undoubtedly a product of an inflammatory process. Its etiology, however, is obscure; the bad hygienic conditions of the mouth may be of importance. The idea, however, that the sublingual growth is an integral part of a definite serious disease does not seem well supported. It is likely that not all affections of the frenulum included under this head are of uniform pathologic character. The diagnosis is easy and the prognosis generally favorable.

51. **The Prostatic Secretion.**—Stern gives a careful analysis of the prostatic secretion, including a special enzyme which has been discovered in it, and shows that it is as yet impossible to single out the specific importance of the prostatic fluid. Possibly it is due to its enzyme exhibiting coagulating properties; maybe to the phosphorus containing lecithin or maybe to some of the nucleoproteids whose importance has still to be determined or to a combined action of any or all of them or to some other factor altogether. There is no doubt, however, as to its physical importance as a vehicle for suspension and the preservation of the spermatozoa. The secretions, however, of other organs, of course, assist, and he thinks it will not be far from the truth in assuming that apart from an eventual specific chemico-enzymic potency, the secretion of the prostate gland is of importance in overcoming the quiescence of the spermatozoa, and in effecting that state of osmosis in the seminal fluid which is essential to fecundation.

52. **Rheumatism vs. Muscular and Joint Fatigue.**—Walsh points out that many cases diagnosed as rheumatism are really cases of muscular fatigue, and shows how this may occur in scoliosis and in hysterical and tubercular joints and in the lungs where the pains are likely to be considered pleuritic. The matter is of importance since the use of depressing antirheumatic remedies is contraindicated in these cases. The treatment of the latter group consists not in the use of analgesics, especially the coal-tar products, but of gentle rubbing and massage and of limitation of exercise of the patient so as to prevent the overuse of respiratory muscles that is sure to be called for if, with one lung practically at rest, the patient attempts any of the ordinary efforts that before were so easy of accomplishment. Resting the parts and tonic treatment are almost always of benefit in all these cases, or exercises to equalize the strength of the muscles.

53. **Orthostatic Albuminuria.**—This condition, which has been described as cyclic albuminuria, albuminuria of adolescence, etc., is discussed in its relation with movable kidney by Sutherland, who reports 15 cases. All of them, he thinks, occurred in patients with a lowered vascular tone and probably venous congestion in the kidneys, altered nutrition and glomerules producing albuminuria. Displacement of the kidney aids the process and the cessation of albuminuria in the reclining posture is best explained by the restoration of the kidney to normal position in this attitude. He mentions that he has met with more cases of movable kidney among forty cases of orthostatic albuminuria than among all the other patients examined at a children's service during fifteen years (15 in 40 cases).

54. **Cold and Blood Changes.**—Weinzirl some time before called attention to the fact that the increased counts of red corpuscles at high altitudes are temporary, and suggests that the temperature may have much to do in their production. He reports experiments on rabbits taken out of a warm basement and carried to a cold temperature and their blood examined. He offers in conclusion the following:

1. Cold is an important factor in accounting for the blood changes due to high altitude. That cold is the only factor, however, is not maintained. 2. In general the specific gravity, the hemoglobin, and the volume of cells follow the increase or decrease of the red blood cells, although this is not invariably the case. 3. Although the data are too few for a final conclusion, there is no evidence that

a decrease in the size of the cells accompanies an increased cell count. The contrary, however, is indicated, and this factor probably varies directly with the others.

65 Chronic Progressive Hemiplegia, with Remarks on Two Cases of Unilateral Paralysis Agitans without Tremor. Hugh T. Patrick.
66 The Work of a Neurological Dispensary Clinic. Smith Ely Jelliffe and L. Pierce Clark.

64. Myoclonus Multiplex.—Dana groups myoclonus under the head of:

1. Myoclonia of Friedreich, or peripheral type, including myokymia. 2. Myoclonia of the functional or hysterical type. 3. Myoclonia of the convulsive tic type, this last type being characterized by many associated spasms, choreic and tonic. 4. Myoclonia of the degenerative chorea or "familial," or myoclonus-epilepsy type, which is closely related with the third. 5. Myoclonia of the type of the infectious and symptomatic choreas. Although there is sometimes a mixture or fusing of the above groups, they are essentially different disorders and, as a rule, can all be easily recognized and easily distinguished from each other. All cases of paramyoclonus multiplex reported as such can be grouped in one or the other. Hence there is no need of that much misused term.

Four cases are described representing each of these types. He reproduces the account of the original case of paramyoclonus multiplex of Friedreich.

70 Hemorrhoids.—Dickinson's method of treating hemorrhoids is, in the case of external piles, to make them as nearly aseptic as possible and then to inject a 5 per cent. solution of nirvanin. Then grasping with the forceps, the hemorrhoid is elevated well up and with scissors curved on the flat, the tumor is cut off close to its base. The base is curetted in order to remove every vestige of the hemorrhoid. The hemorrhage is usually slight and controlled by pressure; if not, hemostatic forceps can be used for a few minutes. When it has stopped, the two sides of the incision can be united with fine catgut, dusted with iodoform and a sterile gauze pad applied and held in place by a T-bandage. It is well to keep the patient recumbent for a few days until the parts are healed. In case of internal hemorrhoids, he operates by dilating the sphincter and applying four Platt's T-forceps, pulling down and outwards with the aid of two assistants, exposing the mucous membrane of the bowel for the distance of an inch or an inch and a half. Each internal hemorrhoid in turn is grasped by forceps, elevated as much as possible and cut off with the scissors, curved on the flat, the long diameter of the incision longitudinal to the bowel. The base of each hemorrhoid is curetted and the hemorrhage stopped with a hot water compress; then dust the parts with orthoform, iodoform and boracic acid. The T-forceps are removed and the lower end of the rectum is packed with a strip of iodoform gauze, two inches wide and two or three yards in length, which has been lubricated with sterile vaselin. The latter makes it easier to remove. It should be removed in twenty-four hours if the patient complains, but as a rule not until after forty-eight hours. When it is removed, hydrogen dioxid should be injected, thus loosening the gauze, and a stream of warm sterile water is allowed to flow over the part. The rectum is daily irrigated with sterile warm water and then injected with half an ounce of olive oil, containing five grains of iodoform. The patient's bowels are moved on the third day by magnesium sulphate. It is not necessary to suture internal hemorrhoids, and when treated in this way they are not very painful. The patient is confined to bed only about a week. The pad and T-bandage are used and make it more comfortable for the patient. He has never had a case of secondary hemorrhage when operating by this method.

73 *The Choice of Methods in the Treatment of Cancer. G. Betton Massey.
74 *The Necessary Co-operation of Heredity and Bacteriology in the Production of Disease. Owen C. Brown.
75 *The Climatologic Treatment of Tuberculosis. Ethan H. Smith.
75½ Daily Study of Foods Producing or Not Producing Casts, Fatty Epithelia and Albumin in Urine. (Continued.) Ephraim Cutter.

73. Cancer.—Massey claims that the massive cataphoric diffusion of mercury under general anesthesia is the most satisfactory way of reducing an accessible growth. The nascent oxychlorids of mercury and zinc are dissolved from electrodes thrust within the growth, causing immediate, sterile necrosis of the growth proper, and sufficient dispersion of the germicidal salts beyond its apparent limits to sterilize the surrounding tissues for an inch or more. All the morbid cells are killed *in situ*, those in the growth coming away as an inodorous slough, while the cells in the surrounding sterilized zone are absorbed as débris. When it is understood that this can all be done in one-half to two hours with practically no after discomfort, he considers we have in it an ideal method for the eradication of the cancer. The choice between this method and the *x*-ray is important in inoperable cases. As a general rule, he thinks the combination of the two methods is desirable, the cataphoresis first, followed by the *x*-ray as soon as the slough comes away, which is in one to three weeks. The destruction and aseptic removal of the growth enables the deeper penetration of the *x*-rays, and prevents the absorption of toxins during the radiation of large growths. In inaccessible cancers, such as those in the nose, mouth, vagina, uterus or rectum, the cataphoric method will have to be depended on alone as a rule.

74. Heredity and Bacteriology.—The object of Brown's paper is to show the co-operation of heredity and bacteriology in the production of disease. He assumes a double tendency in all living beings to variation on the one hand and to conservatism on the other, the latter being what we know as heredity. These tendencies apply equally to disease. They may be dormant in the system for generations. Certain attributes, developments and diseases common to both sexes and certain functions may be arrested by the development of functions peculiar to each sex. They may reappear in the offspring, or be reawakened when the functions of development that had arrested their growth have discontinued their activity. Diseases following developments of structure caused by increased functional activity are as readily transmitted as such increased structural developments. Bacteriology is concerned with environment; bacteria can not be the sole producers of disease. Heredity and bacteriology are mutually dependent and must co-operate if they are to become active in the production of disease.

75. Tuberculosis.—Smith criticises the various climates of the mountainous regions of the west, holding that the altitude in some is too high, while others are too dusty and liable to excessive range of temperature, storms, etc. In Arizona, for example, the conditions are poor for a large class of cases. In California, he thinks the climate has a large range. Some

parts are good for one class and others for others. Many patients receive benefit from traveling with a camp wagon from north to south, and *vice versa*, according to the season. He has known, however, of pulmonary tuberculosis patients going to Alaska and returning well. In all these cases the patients had a good digestion. Where the digestion is impaired the case is hopeless. He insists in conclusion on the importance of fresh air and open-air life. The latter, in tents, is possible for almost any tuberculous patient the year around.

77. **Accouchement Force.**—Williams would not employ premature delivery in cases of deformed pelves, but would rather let them go to term and then, if necessary, perform cesarean section as safer both for the mother and child. In cases of toxemia of pregnancy, eclampsia and placenta previa he considers accouchement forcé indicated, and in eclampsia it is imperatively demanded both theoretically and by practical experience. His experience with eclampsia numbered 30 cases, and the conclusions are briefly summarized as follows:

If the cervix will admit one finger or can be readily dilated sufficiently to do so, accouchement forcé by Harris' method, using the fingers, is a safe and justifiable procedure, if effected slowly. If the cervix is cartilaginous in consistency and apparently offers an insuperable obstacle, it would be more conservative in hospital practice to resort to cesarean section, while in private practice better results will be obtained by palliative treatment rather than by attempting immediate delivery.

In the toxemia of pregnancy he has had to resort to the method in 13 cases, and concludes that in such the pregnancy should, if possible, be terminated by the employment of the bougie or Champetier de Ribes' bag, accouchement forcé being reserved for the very exceptional cases in which danger of the onset of eclampsia is so imminent that very rapid delivery is urgently indicated. In placenta previa he thinks if the child is viable and in good condition and the parents are particularly desirous of saving it, Champetier de Ribes' balloon may be introduced and complete dilatation of the cervix obtained by making traction on it either by means of the hand or a weight. However, this is slightly more dangerous to the mother than bipolar version. In 34 cases accouchement forcé was undertaken for the sake of the child or mother in patients who were already in labor, the indications being hydramnios, pyelonephrosis, intense cystitis, one each, danger to the fetus as shown by sudden change in the pulse rate, or prolapse of the cord in 7 cases, and in 24 very prolonged labor as manifested by exhaustion and marked and persistent elevation in maternal pulse rate or fever. All of the mothers recovered while 28 per cent. of the children perished. He thinks after labor has set in, excepting in cases of placenta previa, accouchement forcé may be undertaken with comparative impunity whenever imperatively necessary. Only 3 deaths occurred in his 87 cases that might be attributed to the operation. Two of these were due to rupture of the uterus, 1 from infection, and there were 7 others where deep tears of the cervix required an immediate operation to control the hemorrhage. He does not believe in the Bossi method of dilatation excepting in very experienced hands, and with Harris' method he cautions against going too fast, as is the tendency. Better results will be obtained by prolonging the operation.

78. **Hysterectomy.**—The question whether the uterus should be removed with the tubes and ovaries is treated of by Mann, who thinks that when the tubes and ovaries have been removed the uterus is unimportant to the patient and she is better off without it. He does not think there is much sentimental feeling in regard to its removal. He ends with quoting Henrotin's dictum: "In any operation for septic conditions of the female generative organs which demand the removal of the tubes and ovaries, hysterectomy should also be performed unless there are contraindications forbidding it."

79. **Shortening of the Round Ligaments.**—The title of this article explains itself, but the details can best be understood by reference to the illustrations. Various methods, such as taking out a wedge-shaped piece from the broad ligaments, buttonholing them, etc., are fully illustrated, there being many modifications according to the needs of the case. He, however, suggests for the whole class of cases the title "Cuneiform shortening of the broad ligaments."

80. **Pelvic Lymphatics.**—Ries proposed the removal of the pelvic lymphatics in case of cervical carcinoma as early as 1895, and has employed the procedure since that time. He finds a number of conditions associated with carcinoma in these glands, and describes the various stages of their invasion by malignant growth. Glandular carcinoma is frequently associated with other conditions, not necessarily always connected with carcinoma, such as the production of epithelial ducts in the lymphatic gland, which he described in his first case operated on. He thinks they may possibly be due to remnants of the Wolffian body embedded in the lymphatics on the posterior pelvic wall. Another condition observed was large cell hyperplasia, which may also occur in tuberculosis, and even in other conditions. He thinks it represents a condition of growth with the nature of which we are not thoroughly familiar. He has also found hyaline degeneration of the connective tissue trabeculæ associated or otherwise with carcinoma, and has frequently found typical hemolymph glands. He believes in the reformation of lymph glands after they have been destroyed or removed, and that they may occur anywhere in the connective tissue. The hemolymph glands, with their direct connection with the blood currents, afford a new explanation of how carcinoma may form metastases.

82. **Hysterectomy.**—Noble's opinion in regard to the removal of the uterus in case of pus tubes is similar to that of Mann. He points out the superiority of the operation over removal of the uterine appendages alone.

83 *A Clinical and Bacteriologic Study of a Number of Outbreaks of Dysentery in which "Dysentery Bacilli" Were Found. William H. Park, Edward K. Dunham and H. M. Carey.

83. **Dysentery.**—Park, Dunham and Carey give the results of their study of the dysentery bacillus, from which they have deduced the following conclusions: At least two distinct varieties of bacilli are found in the intestines of those suffering from dysentery and colitis which have not as yet been met with in other conditions. They differ from each other in certain cultural characteristics (indol formation and mannite fermentation), and also in their agglutinating reaction. Different cultures made at widely separated places, though agreeing in their agglutinating reaction with most sera, still differ from each other when tried with various normal animal sera. Though Martini and Lentz are right in their statement that the Shiga type differs from Flexner's Manila Baltimore type in cultures and agglutinative reaction, yet they seem to be altogether wrong in concluding that any one type is more a factor in dysentery than the other. Indeed, the Deycke bacilli from Constantinople dysentery, which approached the colon type in cultural characteristics, can not be overlooked. The authors think it probable that Shiga, if he carries his cultural and agglutinative tests as far as necessary, will find that not one but several varieties are present in the intestines of different and perhaps the same patients in Japan as well as in the United States. The use of more accurate agglutinative tests along with additional culture media has shown that in different epidemics the bacilli found vary so greatly from the

Shiga cultures that it can hardly be determined whether or not it can be brought within one single dysentery group.

85. The Washing-Out Plan.—Haig protests against the adoption of the washing-out plan in nephritis and other conditions, especially those of uric acid disease. He thinks in Bright's disease the better treatment is the cutting off of all fluids, putting the patient on even as little as a half pint of fluid in twenty-four hours. He calls the idea of washing out the system silly and unphysiologic.

1. **Milroy Lecture on Tuberculosis.**—In concluding this series of lectures, Bulstrode states that England has about sixty institutions, public or private, at which cases of pulmonary tuberculosis may be accommodated. The number of beds is probably under 2,500, outside of workhouses and infirmaries. He describes four typical sanatoriums in detail, with their workings. The one at Westmorland has accommodations for 24, and 21 of the beds have been appropriated by various local authorities in the county at a rate of about $300 (£60) per annum for each bed. As these are never all filled, "outsiders" are taken in at a charge which provides a slight margin of profit. The usual length of stay in the early cases is twelve weeks, in the moderately advanced eighteen weeks, and in the quite advanced cases twenty-four weeks. The curative value of the institution is diminished by the presence of the advanced cases which, although staying some six months in the institution, are of but little use, in a working sense, thereafter. Of the 91 patients treated during the last two years, 53 are at work, 17 at home and 21 have died. This includes 45 "cavity cases" and 46 "consolidation cases." He gives statistics to show that the expense to the state would be much less if incurable cases were placed in separate institutions. He advocates as the most important measures for the control of pulmonary tuberculosis as a matter of public health: 1. The education of older children in the principles of health and the periodical physical examination of all school children, with a view of improving the health of those prone to tuberculosis, or who may already be suffering from the disease in an unrecognized, though not unrecognizable, form. The direct and indirect results which would accrue from this would soon make themselves felt in the direction of an unwillingness on the part of people to occupy slums or to dwell in places where the sun rarely penetrates. It would also result later in the election of representatives who would be more alive to the importance of the public health aspect of their duties than is always the case at present. 2. Some such system of compulsory insurance against sickness and invalidity as obtains in Germany and which, it is important to note, makes for the provision of sanatoriums, the support of those threatened with illness and the general well-being of the poorer classes. 3. Better housing and improved conditions of employment of the working classes.

2. **Infantile Scurvy.**—Colman thinks that certain toxic substances may be formed in milk by the various modes of preparation, or in other provisions, which may favor the occurrence of hemorrhagic lesions. The products of decomposition (not necessarily offensive) are possibly subordinate factors in the production of scurvy, although the essential one is the absence of sufficient fresh vegetable and animal food. The treatment in children consists solely in rectification of the diet, for which he advises, in addition to fresh milk and cream, a potato soup made by cooking a potato without peeling, passing it through a sieve and then pouring over it a cupful of boiling milk and adding a little sugar if the child likes it sweet. The limbs should be placed between sandbags if badly swollen, to keep them from being moved, or the hand and forearm may be bandaged to the side. Treatment of accompanying rickets should be postponed.

3. **Action of Hemolytic Sera.**—Muir's research was undertaken in order to study more closely than has been done the combined relationships of the immune-body and the complement, and the possibility of dissociating these substances singly or together after they have combined. The sera used in most of the experiments were those of rabbits, immunized against the red corpuscles of the ox. He found that the immune-body and the complement differed markedly from each other in their mode of combination and the firmness of union. The immune-body can be in part separated before hemolysis from red corpuscles containing multiple doses, but the complement after its union with the cells can not be separated again.

6. **Sanatorium Treatment of Tuberculosis.**—Burton-Fanning reviews two years' experience at the Mundesley Sanatorium, and reiterates the importance of the early recognition of pulmonary tuberculosis. If adequate measures are taken in the very earliest stages of the malady we may hope to restore some 75 per cent. of our patients to more or less lasting fitness for work. In about 90 per cent. of these favorable cases the disease is sufficiently mastered to allow of the patient's life being indefinitely prolonged, but the maintenance of his ascendancy over the bacillus depends on his living by rules based on careful observation of individual requirements and powers. He must expend in other ways no more energy than can safely be spared by the forces required to keep his malady in check, and he must take no liberties with health. The supreme importance of these and other principles of sanatorium treatment is apt to be lost sight of by those who rely on mere change of climate in the treatment of consumption.

7. **Summer Diarrhea and Vomiting in Infants.**—Hicks believes that babies with this summer complaint suffer and die mainly from thirst. Their intestines extract water from the circulation and the circulation from the tissues, while the fluid supply is cut off by the damaged alimentary canal refusing to tolerate the input. All treatment then is directed against the cause, to clear out by the least irritating means the toxins which are the primary cause, and at the same time to introduce a fluid that can be retained and absorbed. Drugs have shown themselves to be of very doubtful assistance in his experience with one exception—oleum ricini, and this seemed most effective given in one initial aperient dose followed after a day by a course of from six to eight six-hourly dram doses of the mistura olei ricini, B. P., with the addition of sodium bicarbonate 2 grains to each dose. Ordinary cases generally respond to the following treatment: After a warm bath, with the child's head hanging over the side of the cot, the stomach is washed out with slightly alkaline water. When this comes away clear, there are passed down the tube one dram of oleum ricini and an ounce or two of albumin mixture with a dram of beef juice or raw meat juice. If the food is rejected small quantities are given even as frequently as a dram every quarter of an hour. If the baby continues to be sick the beef juice is omitted, and if vomiting still persists, all feeding by the mouth must be stopped and intracellular infusion of normal saline solution adopted. In the severe cases the saline solution is commenced at once, about four ounces every six hours with—if absolutely necessary—the addition of a very little brandy. Infusion of a small amount is more beneficial than one of half a pint or more, and it is important to infuse extremely slowly; washing out of the stomach must be left until the patient's condition permits it, but small enemata of normal saline solution have proved decidedly beneficial. If brandy has to be ordered it is administered hypodermically. Babies are bathed twice a day, moving them as little as possible. Except for the bath the baby is kept in absolute seclusion in a curtained bed. Another point in treatment is the thorough scrubbing and disinfecting of the nurse's hands after having attended to the infant. By infecting the food with even the smallest particle of fecal matter, the sickness, which has just been stopped with great difficulty, may be started again. Another experience which he has had in obstinate cases of habitual vomiting is that some infants will not reject their food if it is introduced by the nasal tube. The formula for the "albumin mixture" mentioned is: To the beaten whites of two fresh eggs, one pint of cold, sterile, normal saline solution is added, the whole then stirred and strained through muslin. In chronic cases he has found a malt soup very satisfactory. This is made by mixing 13 drams of wheat flour with 12 ounces of cow's milk, straining through a hair sieve. In another vessel 3 ounces, 2

drams of extract of malt are dissolved in 24 ounces of water at 122 F. and to this is added 2.5 drams of an 11 per cent. solution of potassium carbonate. The two preparations are then mixed and boiled up quickly. Babies can be kept on this food for three weeks.

8. **Dysentery Cured by Aplopappus Baylahuen.**—Fingland describes three cases cured by an extract of a plant indigenous in South America, called locally hysteronica. It belongs to the class of balsams. The curative effects of the drug were so conspicuous that he believes it is liable to prove a specific for sporadic dysentery.

11. **Relation of Vaccination to Infant Mortality and Acute Concurrent Infantile Diseases.**—Mackenzie tabulates the statistics of 987 infants less than one year old living and dying in a certain district. Of this number 706 had been vaccinated. The tables show that the death rate among the unvaccinated, especially in the early months of infant life, was far in excess of that among the vaccinated. He does not claim that vaccination will keep babies alive, but the facts demonstrate that it does not kill them. The probable explanation of the lesser mortality is that the weaklings are not vaccinated. Experience has shown also that the vaccinal process acting concurrently with another disease is modified in its onset and ushered in by no shock. There is nothing to be observed corresponding with the rigors of adults or the convulsions of infants at the onset of acute disease, and the general course is milder. Measles, scarlet fever, whooping cough and influenza seem to be favorably modified by the vaccinal process, while the latter is unusually mild. In cases of congenital syphilis the pocks were slower in their development, and took longer to scab and heal up. Contrary to the other diseases, the influence of zymotic enteritis seems to be unfavorable. Unsanitary dwellings, overcrowding and filthy habits are immensely more dangerous to the recently vaccinated than the presence of such diseases as scarlet fever, measles, whooping cough and influenza. Mackenzie has also noticed that vaccination is liable to excite dormant eczema and impetigo. Ill health, particularly anemia, is a very common cause of insusceptibility; let anemia be corrected and the child will soon be successfully vaccinated. He concludes with the question which he does not attempt to answer: Granted that acute concurrent diseases modify the vaccinal process, tone down the symptoms and delay the evolution of the pock, does it follow that in these cases it also modifies the protection which vaccination affords?

14. **Physical Degeneration of Children of the Working Classes.**—Tidswell affirms that the standard of health among the school children in the large towns of England is not so high as it ought to be at the present day, considering the advances in sanitation, etc. He says that he has frequently been impressed with the expressions of the children coming out of school. Only a few had an expression of joy and happiness. The majority had a sad, careworn, haggard look, suggestive of mental strain. He urges systematic medical inspection, a medical officer attached to each school, who shall inspect each class as it assembles to detect infectious or other diseases in the early stage, who shall examine the eyesight, hearing and general condition of each child and keep a report of the same, who shall visit any pupil at home in case of sudden illness and give certificate to same. In the end such a measure would be true economy; it would save a vast amount of suffering and help to raise the standard of national health.

15. **Excision of Cecum.**—Paul operated on 3 out of 6 cases of cancer of the cecum observed since Christmas. Nearly all the cases of chronic stricture of the large bowel, in his experience, have been at one time regarded as cases of stomach derangement, sometimes even when the stricture was in the rectum. The earlier symptoms are dyspeptic in character and vomiting after food is not infrequent. Later, when colic is marked, the intestinal origin of the mischief should be apparent, though it is often not recognized until obstruction occurs. The recognizable symptoms really depend on the amount of obstruction offered by the growth and its detection on palpation. Obstruction more than trebles the danger in colectomy. The location of the tumor is rendered difficult or impossible, operation is prolonged and impeded, and the chance of infecting the peritoneum is increased, in addition to the depressing effect due to the absorption of toxins developed in the bowel during the period of obstruction. To have a fair chance the surgeon should undertake the resection before obstruction supervenes. The cut end of the colon sometimes sloughs from interference with the circulation from removal of the mesentery, and this is a strong argument in favor of bringing out the ends of the bowel and establishing a temporary artificial anus. He used to suppose that enlarged mesenteric glands in the vicinity meant an ultimately hopeless prognosis, but two of his patients who presented them are still in good health, one after two and a half and the other after four and a half years. In conclusion he describes his last three cases and a new clamp for removing the spur. The blades are 3 inches long, curving out at the ends, and the compressing force is regulated by a spring and screw nut. The slough is produced in twenty-four to forty-eight hours.

17. **Lymphatic Varices During Pregnancy.**—Tuffier relates a case of a lymphangioma in the right inguinal-crural region in a woman of 40, in the fifth month of pregnancy. The tumor had rapidly increased in size, and knowing the almost fatal gravity of infection of lymphatic varices he extirpated the tumor under spinal cocainization by his present technic (using a 12 per cent. solution diluted in the cerebrospinal fluid). Two small, transparent vesicles were discovered in the region six months later, relics and testimony, he considers, of a preexisting ectasia of the lymphatics, which under the stress of the pregnancy had developed into large varices.

19. **Results of Operations Liberating the Radial Nerve After Fracture of Humerus.**—Launois and Lejars describe and illustrate a case in which the radial nerve was enclosed in a sheath of new bone formation, entailing paralysis, hard edema and painful contraction of the hand. An operation to free the nerve was undertaken four months after the fracture, and function was gradually restored, the cure being complete by the end of eight months. Blencke has recently published statistics of 68 similar operations to liberate the radial nerve after heal-

ing of a fracture. In 41 the cure was complete; in 6 nearly so; in 8 there was marked improvement, and in 3 slight improvement. In only 7 cases were the results negative. In 3 the outcome was not known. This is a proportion of cures or improvements in 58 cases, or 85.3 per cent. Intervention should be early, although excellent results have been obtained even at a late date. If neuritis develops or a sclerous perineuritis, the longer the delay the more serious the resulting injury of the nerve. Another reason for operating early is the progressive atrophy of the muscles, stiffness of the joints and trophic disturbances which constantly progress. It is advisable to undertake massage and exercises of the joints when first seen, without waiting for the operation. A long interval elapses after intervention before any result is apparent. Usually from four to six months passes before restoration of function, after either liberation or suture of the nerve. The patient should be warned that he will not note any difference before six months, and even later than this, success should not be despaired of. Polaillon's patient was operated on six weeks after the injury, but voluntary movements were not possible until two years later, and the arm then regained its normal strength. Blencke's personal case seems to be a remarkable exception to this rule. On account of a typical radial paralysis, four months after the fracture the nerve was exposed. It was found encased in cicatricial tissue, which pressed it against a projecting point of bone. It was liberated and the surface of the bone leveled, with almost complete restoration of function in forty days. The operation should remove all traces of the fibrous sheath, cicatricial tissue or bone growth encroaching on the nerve. The bony canal in one case was 5 cm. long, in another 4 cm. In Blencke's statistics the nerve was torn across in 12 cases; in 10 it was sutured, with complete success in 7 and improvement in 2 others. Restoration of function was complete after two months in 1 case; after seven in 1; nine in 1; ten in 2; a year and a half in 1, and two years in 1. Trendelenburg found the gap between the stumps too long for suture in 3 cases, and brought them together by shortening the humerus. In one instance the gap was 7 or 8 cm., and he resected 5 cm. of the bone "en escalier"—staircase fashion, after which the bone and nerve could be sutured without difficulty. Function was restored after ten months. In the 2 others the nerve was not torn, but was so degenerated that a segment of 4 to 6 cm. was excised. The results were equally fine in one case, but sufficient time has not elapsed in the other for complete restoration. Wölfler has reported a similar operation with no benefit nearly three months afterward, but complete motor restoration was realized by the end of the second year. The cicatricial focus must be excised, as recurrence is liable. Wölfler had to operate three times on one of his patients. Final success was attained after enveloping the nerve in strips of epidermis taken from the thigh. Launois does not approve of the introduction of a foreign body to protect the nerve, believing that better results will be obtained by extensive extirpation of the cicatricial focus. Ollier used to advocate detaching a strip of periosteum where the bone approaches the nerve. It may be advisable to level the bone or chisel a groove in it. Reisinger has in 2 cases sucessfully transferred the nerve to a groove in the soft parts. In one instance he cut a flap in the triceps and brought it down over the nerve, in the other he hollowed out a groove in the muscle and, after placing the radial in the groove, sutured the two edges above it. There was suppuration in one case with expulsion of several sequestra, but by the end of eleven months functional restoration was complete.

20. **Occlusion of Intestine from Kinking of Left Angle of Colon.**—Berard and Patel have observed at Lyons a case of occlusion of the intestines caused by sinking down of the colon each side of the left angle, which was held in place by the ligaments. As the gut droops the angle, instead of being rounded, becomes sharp and the gut folds on itself, almost or entirely closing the lumen. The lesser the width of the suspending ligament the sharper the angle becomes. Pain at the seventh or eighth rib seems to be the only sign which indicates an obstruction at this point. If the occlusion is not total, injections of oil and other medical measures may relieve, and the symptoms sometimes subside after a copious evacuation of the bowels. To avoid recurrence, the stools should be regulated, and as there is usually general enteroptosis and nephroptosis a large, double, well-fitted Glénard belt may be found useful. In one of the two personal cases described this belt is proving a true medical colopexy, removing all disturbances from this cause. In case of a laparotomy for occlusion if no neoplasm or constricting bands are found, this essential occlusion at the splenic angle should be thought of. When discovered it may be cured by lateral entero-anastomosis or colopexy, or both combined. Two other cases found in the literature are also cited.

21. **Treatment of Wounds of Diaphragm.**—Whenever there is a probability that the diaphragm has been involved in a wound, it should be opened up through the thorax and the wound sutured. By this simple intervention hernia later is prevented. Lenormant has thus treated 2 patients and tabulates 8 others treated by a laparotomy and 21 operated on by way of the pleura like his own cases. There were 5 deaths in the first group and only 3 deaths among the 23 in the second group. He gives the details of the entire list of 31 cases.

22. **Idiopathic Dilatation of Large Intestine.**—Duval is prosector at Paris and his extensive monograph is concluded from the March and April numbers. He has collected 48 cases of Mya's congenital megacolon, Hirschsprung's disease, or idiopathic dilatation of the large intestine as it is variously called, including some that have been published in this country. In 4 the condition was congenital and in 38 it dated from early infancy. In 5 only it was noted later, at the age of 15, 24, 32 or 50 and "in an adult." The colon in Formad's case contained 47 pounds of fecal matters; in Fütterer's the colon measured 66 cm. in circumference and had a capacity of 16 liters. Medical treatment should be perseveringly attempted, large daily injections carried into the colon and purgatives avoided except possibly oil. Electricity and massage may be useful, but only one case is on record in which daily stools were obtained by these measures. Hirschsprung reported benefit after six months. Failures are frequent. In the 15 cases in which surgical intervention was attempted 4 deaths occurred. Colopexy proved successful in 2 out of 4 cases in which it was tried, colectomy in 2 out of 5, and colostomy in 2 out of 4.

26. **Method of Reaching Abscess in Liver.**—Mendes reports a case cured by evacuating the abscess in the liver by a parapleural transdiaphragmatic operation. He recommends this method as allowing perfect drainage while absolutely avoiding immediate pneumothorax and infection of the peritoneum. He turned back a flap of bone and soft parts corresponding to the seventh interspace, and then resected the eighth and ninth ribs. The pleura was detached and pushed out of the way and the exposed diaphragm was incised for 5 cm., allowing the escape of 423 gm. of pus. The parts were swabbed and two large drains carried into the focus. The drains were expelled by the ninth day and the last traces of the wounds healed in less than a month.

29. **Actinomycosis of Liver.**—Auvray states that potassium iodid has failed to benefit the cases of actinomycosis of the liver that have been published, but still it should always be given a trial, using as much as 6 to 10 gm. a day. In 6 cases an operation was undertaken, in 4 a laparotomy, a lumbar incision in 1, and through the thorax in another. None of the patients were saved.

34. The Wounded in the Wars of the Fifteenth and Sixteenth Centuries.—Brunner's article is a comprehensive illustrated, historical review of the treatment of the wounded and of military medical and surgical affairs generally in the various campaigns of Europe before 1600. His facts and illustrations are derived from old chronicles, paintings, frescoes, stained glass windows, etc., and form a most interesting portrayal of the conditions then prevailing. The wounded were abandoned to the conquerors. The first attempt to depart from this barbarous practice seems to have been by the Swiss at the battle of Marigniano during the early part of the sixteenth century. In their defeat they carried their wounded away with them.

35. Curvature of Leg After Resection of Knee in Children.—Hofmeister was able to examine 107 of his little patients from one to seventeen years after resection of the knee. He found severe curvature of the leg in 44 per cent. and medium in 72.7 per cent. Only 16.8 per cent. were absolutely and 27.1 comparatively straight. The tendency to curvature diminished with the age of the subject. Between 3 to 8 the percentage was 64.6 per cent. of severe curvatures, while from 9 to 13 it was only 27.2 per cent. He attributes the curvature and physiologic weakness of the bones to the weight of the body and the traction of the flexor muscles. Prolonged after-treatment is necessary in prevention, and he believes that it would be advisable to detach the flexor muscles from the thigh when knee resection is undertaken on children under 8.

36. Isolated Involvement of Appendix in Hernia.—Honsell has observed 4 and collected 79 cases of this condition in the literature. He advocates removal of the appendix under these circumstances, even if sound, as it is liable to be injured and entail appendicitis later.

37. Primary Cancer of the Extremities.—Brunn reports from Tübingen a number of cases, bringing the total statistics of the clinic to 46 cases, with 35 per cent. permanent recoveries. Metastasis in the lymph glands is rare, but still sometimes occurs. Several inoperable recurrences were due to this cause. Most of the cancers developed on a chronically inflamed soil, but a few after a single trauma. The right upper extremity was the most frequent site. The number of permanent recoveries is about the same after mutilating and conservative operations, if the successfully operated recurrences are included. He reviews in conclusion 145 cases not included in Volkmann's statistics.

38. Relations Between the Suprarenals and Growth.—Linser argues to prove that the thyroid, hypophysis, thymus, suprarenals and sexual glands are intimately connected and may mutually influence and functionally supplement each other. Also, that there is a connection between these glands, and especially the suprarenals, with growth. In giant growth there is usually a tumor in one or more of these glands, while in dwarf growth there is usually hypoplasia or aplasia. He describes 2 cases which apparently confirm this view.

40. Pseudo-Appendicitis.—Küttner found the appendix and its surroundings completely normal in 3 cases deceptively simulating appendicitis and operated on after subsidence. He is convinced that such cases occur more frequently than is appreciated. Helminthiasis, colics, oxyurides in the appendix, and gases distending the ileocecal region are liable to simulate appendicitis, and muscular resistance in the region may be due to circumscribed contraction of the rectus muscle. The curative effect of many operations in which the appendix is found histologically sound is probably due, he thinks, to severing of certain nerve branches or possibly only to the rest in bed, change of diet and suggestion.

41. Healing of Wounds and Defects in Tendons.—The danger of secondary stretching imposes prolonged immobilization in the treatment of severed tendons or tendon wounds in general. Whether four weeks is enough Seggel considers dubious, from his experience on guinea-pigs. Even forty days are not a long enough interval to ensure safety in functional use of the parts. The tendon sheath plays an important part in the healing which proceeds much more rapidly when the sheath is uninjured. Regeneration of defects does not occur until after reactionary hyperemia, and does not seem to be influenced by the presence of a foreign body, but to be the inherent property of the cells.

42. Healing of Unpedunculated Skin Flaps.—Braun shows by the results obtained in several cases that unpedunculated skin flaps may heal perfectly in place and stand the severest strain, as, for instance, on the heel.

43. Nervous Symptoms Cured by Operation for Colitis.—Lindner has observed several cases of neurasthenic and hypochondriac conditions entailed by chronic colitis and completely cured by an operation on the colon. He regards them as neuroses from chronic obstipation.

44. Resection of Large Intestine in Several Sittings.—Goeschel has operated on 4 cases by this gradual method. One was a carcinoma of the cecum, one of the colon, one of stenosis of the colon by a chronic, hemorrhagic infarct and one a tumor on the adnexa grown to the cecum and appendix. After resection of the intestine he found the continuous bath very useful.

51. Treatment of Cavities in Tibia and Calcaneus.—Bayer transforms the cavity into a broad shallow groove, pushing back the soft parts to allow the bone to be modeled to the required shape, rounding the sharp edges of the bone on each side of the groove. The two flaps of skin and periosteum on each side are then turned down over the edge of the bone on each side and fitted into the groove, which they cover except for a strip down the center. A roll of gauze is then laid in the groove on top of the turned-over flaps, held in place by a few interrupted sutures taken in the skin, which also draw the flaps closer together. They heal in place under the pressure of the roll of gauze much more rapidly than by any other method of treatment, and the gap in the center of the groove

soon skins over. The outer dressings are not renewed for eight to ten days.

54. **Mobilization of Duodenum for Intervention on Biliary System.**—Lorenz has been testing on the cadaver Kocher's suggestion of mobilizing the duodenum described in THE JOURNAL, xl, p. 613. He finds it simple and easy of accomplishment while the benefit is great, and commends it as a valuable aid for cholecystenterostomy, rendering the latter an easier operation even than a cholecystogastrostomy. It also allows the choledochus to be brought nearer the surface. Its most important use, however, is to allow free access to the retroduodenal portion of the choledochus.

55. **Treatment of Fistula in Descending Portion of Duodenum.**—Berg points out that the lack of peritoneal covering at this point of the intestines renders the repair of a perforating ulcer here a difficult matter. He suggests treating this condition by establishing a gastrojejunostomy and tying off the pylorus with a tobacco-purse suture. This would prevent the escape of chyme through the fistula, while retaining the benefits of stomach digestion. (The priority for this operation is claimed by Cackovic in No. 25.)

56. **Massage of Heart in Chloroform Collapse.**—Zesas states that massage of the exposed heart is theoretically contrary to what we know of the mechanical action and physiology of the organ. In practice, also, no permanent successes have been recorded. He disapproves of it and believes that better results will be attained by devoting the entire attention to the usual measures of resuscitation. About a dozen cases have been reported in which massage of the heart was tried and he adds another to the list, remarking that it dates from the 80's and was thus the pioneer of all. The patient was a robust man of 40 who wished to be relieved of a goiter that interfered with swallowing and breathing, otherwise perfectly healthy. Niehaus was the surgeon. The chloroform narcosis proceeded normally, but, before the operation commenced, the respiration and heart stopped and all measures, including resection of ribs and rhythmical compression of the heart, proved ineffectual to resuscitate the patient.

57. **Amputation of Penis.**—Hopmann describes the success of the Bardenheuer method of amputation as evidenced by a patient seen recently nine years after the penis had been amputated on account of cancroid. There has been no recurrence and the method absolutely prevents stricture. The principle of the operation is to leave the urethra, detached from surrounding tissues, projecting for 2 cm. from the stump. The skin flap is then sutured around the base of the urethra without including the urethral mucosa in the suture. During the healing process the edges of the projecting portion of the urethra curl over outward, thus producing a wide and permanent orifice. Four other cases in which this method has been followed show equally favorable results.

58. **Rutkowsky's Method of Gastroenterostomy with Gastrostomy.**—Hammesfahr has combined these two operations, as suggested by Rutkowsky, and confirms the latter's statements in regard to the simplicity of the intervention and the prevention of the vicious circle. His experience now includes 12 cases of chronic stenosis of the pylorus or an ulcer or carcinoma at this point, operated on by this technic, and he has always been gratified with the results.

61. **Adrenalin and Local Anesthesia.**—Honigmann reports experiences which confirm Braun's announcement in regard to the way in which the addition of adrenalin to cocain immeasurably enhances the anesthetic action of the latter.

65. **Treatment of Indentation of the Skull in the Newborn.**—Baumm has used in 4 cases a small corkscrew to raise the indented portion. The instrument is made specially for the purpose with the turns close together and it is inserted only far enough to hold. The procedure is harmless and has proved effectual.

68. **Physiology of Fertilization, Parthogenesis and Development.**—Schücking relates experiments on echinoderms (*Asterias glacialis, Arbacia pustulosa* and *Strongylocentrotus lividus*), which establish that the processes which induce development of the ovum may be traced to a number of mechanical and chemical actions, and that development is independent of fertilization. He found that the head of the spermatozoön does not bore into the ovum, but becomes surrounded by a hyaline process of the protoplasma and is sucked into the ovum. The development of the ripe ovum is started by absorption of water. Fertilization occurred with spermatozoa placed on the ovum, deprived of their tails. Parthogenesis may be induced by various external stimuli, chemical, thermic or electric light. Relaxation follows the stimulation, and in this stage water enters and starts the development. He found the best medium for the study of parthogenesis to be sea water to which acetic acid had been added in the proportion of one or two drops to 200 gm. sea water.

75. **Circular Ligature of Vagina for Retroflexio.**—Schücking noticed that the uterus in sliding into retroflexion pushes the vaginal wall downward, and reasoned that if the vaginal wall offered a resistance the retroflexion could not occur. He has treated a number of cases on this principle and the results surpassed his anticipations. His technic consists in making a buried circular ligature each side of the portio and in the posterior vaginal vault. He uses silver wire and removes it after four to six weeks, ordering a small pessary to be worn for a time afterward. The procedure is too simple to be called an operation and seldom requires narcosis. The needle is passed around in a circle under the mucosa, emerging at its entering point, or inserted in two semicircles. In large vaginæ he sometimes makes as many as six of these circular sutures. The result is two folds at the side, which hold the portio firm, and a cicatrix in the posterior vaginal vault, which offer a resistance to the pushing down of the vaginal wall indispensable to retroflexion.

78. **Anesthol.**—Foerster commends to his compatriots the method of anesthesia which Willy Meyer described in the last volume of The Journal, p. 553.

79. **Vomiting of Pregnancy and Hysteria.**—Feinberg relates 2 cases of hyperemesis gravidarum in which he believes the idea of hysteria as the cause of the condition is absolutely untenable.

80. **Retroflexion Operation.**—Alexandroff advocates shortening the broad ligaments as the rational method of remedying retroflexion. He passes a provisional ligature through each of the ligaments, 3 to 3.5 cm. from the collum, and draws them down by pulling on the crossed ligatures. The ligaments thus brought into contact and shortened are sutured together over the anterior surface of the collum, including some of the latter in the suture which must never pass beyond the internal orifice. The uterus retains its entire movability by this operation, while retroflexion is prevented and no disturbances of any kind followed in the cases thus treated.

81. **Pregnancy Icterus.**—Brauer reported a year ago a case in which hemoglobinuria recurred at each pregnancy, and now describes another in which icterus was observed about the fourth month in four pregnancies. In both cases the condition was accompanied by symptoms indicating general derangement, but all vanished after delivery.

85. **Etiology of Carcinoma Vaginae.**—Maly observed a case in which a carcinoma developed in the vagina at the point of greatest pressure from a pessary. It was a ring of soft rubber and had been worn for thirty-nine years.

90. **Microscopic Technic.**—Zepler has found it a great improvement to use an ordinary wire sieve for sections, as it allows a large number at a time to be submitted to the various staining and rinsing procedures. A still further improvement is to use instead of the sieve a white porcelain or glass vessel perforated with numerous small holes. The sections are more easily taken up from this than from a sieve.

94. **Family Arsenic Poisoning.**—Three members of the same family reproduced the same clinical picture of paralysis after the entire family had suffered from symptoms of poisoning from arsenic in the flour. The other members recovered without paralysis. It was evidently the result of a toxic neuritis in the mother and two children affected.

98. **Synorchidia in Conservative Operations on the Testicles.**—Pascale has experimented on animals and the results have been confirmed in the clinic, demonstrating that it is possible to unite the two testicles and that a single vas deferens will suffice for both. This retains the gland and its internal secretion and allows the latter to issue by the natural channels, while the parts most liable to be infected by a tuberculous process in the epididymis may be removed. His technic is the systematic resection of the entire tuberculous epididymis and vas deferens on the side affected, leaving the vessels and nerves intact. He then opens up the rete testis and determines the integrity of this part of the gland before proceeding further. This portion of the gland is then implanted on the part of the sound testicle opposite to it, which is very easily done after removing the intertesticular septum. In 4 cases treated in this manner the results have fully confirmed the successes on animals previously published. They establish that the functional activity of a testicle thus implanted on its mate is maintained even after complete extirpation of its vas and epididymis, retaining the vascular and nervous elements. He calls this union "synorchidia" and adds that the vessels in the rete testis of the corpus Highmorianum retain their normal current, as they open at the base of the spermatic lobules, and the current passes through them and the straight tubes to the corpus Highmorianum of the testicle on the sound side, merely doubling the length of the normal route. Scaduto has published good results from implanting the vas deferens in the testicle after ablation of the epididymis, but Pascale thinks that this exposes to greater danger of inoculating the testicle. The indications for this synorchidia are tuberculous or other processes or tumors in the epididymis.

99. **Cryoscopy.**—Ferrannini has been studying the determination of the osmotic tension of the blood and organic fluids by means of cryoscopy, and points out various sources of error in the findings and means to avoid them. He thinks the results will be more harmonious if a standard freezing mixture is adopted, such as ether, the evaporation regulated by a stopcock admitting air, as in Raoult's apparatus, or a mixture of 20 per cent. sodium carbonate with the ice, which ensures a temperature of minus 2.015 degrees C. The fluid to be examined should never be diluted, and the attempt should not be made with a quantity less than 8 c.c. It is immaterial, he has established, whether the blood serum or merely defibrinated blood be used for the test. In the latter case a smaller amount of blood is required. It is important also to have the air in the test tubes dried beforehand to prevent variations from different degrees of evaporation. It is indispensable to stir the fluid while it is congealing, and this vertically. This is done with a glass rod through the stopper of the tube, and in order to ensure the non-admittance of air he has the rod pass through a bag of thin rubber, one end of which is tied to the tube.

100. **Bacteriuria in Animals.**—Ferrannini relates that he found various micro-organisms in the urine of every one of a number of rabbits and dogs he examined.

102. **Membranous Croup from Pneumobacillus.**—The case progressed to a fatal termination uninfluenced by antidiphtheria serum treatment. Large numbers of Friedlander's pneumobacillus were cultivated from the false membranes.

105. **Anchylostoma Anemia.**—Gabbi, three years ago, announced that the blood of subjects with anchylostoma anemia had a destructive action on the red corpuscles of the rabbit. He has found since that this destructive action occurs also with the red corpuscles of debilitated human subjects. The toxicity of the urine is also increased, the alcoholic extract inducing gradual fatal anemia in rabbits. The anemia in anchylostoma infection is due at first to the repeated losses of blood, but is maintained by imperfect regeneration of the blood in the bone marrow and by the slow destruction of the red

corpuscles in the vessels owing to the hemolytic power of the blood serum in this condition.

106. **Action of Gastric Juice on Tubercle Bacilli.**—Ferrannini's experiments with guinea-pigs showed that human gastric juice, even with as much as 2 per 1000 free hydrochloric acid, had no inhibiting action on tubercle bacilli. Tuberculosis followed in every instance after ingestion of bacilli mixed with gastric juice in conditions approximating those in the human stomach.

107. **Picric Acid in Uterine Gonorrhea.**—Serra reports 21 cases of gonorrheal urethritis, with metritis, bartholinitis or vulvovaginitis, including 5 cases in which the gonococci were not found, but otherwise presented the same picture. All were treated with injections of a 12 per 1000 solution of picric acid, and he found the results very satisfactory. It destroys the gonococci and they vanish early if treatment is commenced promptly. The injections are made about twice a week, with a Braun syringe holding 5 c.c.; the fluid is injected into the uterus and the vagina tamponed with gauze removed the next day. His patients were cured with one exception in from ten to forty-five days, and there has been no recurrence since. These intrauterine injections are not irritating, but have a decided analgetic action, and for their other advantages, inexpensiveness, reliability, stability of the preparation, etc., deserve more general adoption. He describes his cases in detail.

108. **Metabolism in Infantilism.**—Ferrannini concludes this long article with its numerous tables with the warning that we must not confound the Lorain type of infantilism with the myxedematous or Brissaud type. The Lorain type may be tuberculous, syphilitic, malarial or toxic in its nature, or what he calls angiodysplastic infantilism. There are two varieties of the latter, the pulmonary and the mitral. In his research on a case of this mitral kind he found the metabolism abnormal in that it corresponded to an age younger than that of the patient.

109. **New Phenomenon in Case of Adams-Stokes Disease.**—The phenomenon which Zeri qualifies as new is that for hours at a time there was perfect synchronism between the pulse and heart beat and the respiratory movements. The heart, the pulse and the inspiration had a simultaneous rhythm. Between the inspirations the tracing of the heart action was nearly a straight line.

113. **Induced Elimination of Sodium Chlorid in Nephritics.**—De Grazia reports tests with five nephritic patients which establish that alimentary chloruria may be a valuable indication of the functional condition of the kidney. In 2 cases of chronic interstitial nephritis the results were different. In one, after ingestion of 10 gm. of sodium chlorid, there was no increase in the elimination of salt the first day, and only a very slight increase the next, while in the other case the kidney was stimulated to eliminate 14 gm. more of the chlorid than ordinary, the amount rising from 17 to 31 gm. The water also increased in proportion and the phosphates and nitrogenous elements. In chronic parenchymatous nephritis the kidney did not respond in any way to the salt taken nor in a case of valvular disease with slight evidences of chronic nephritis. In every instance the kidney responded abnormally to the test.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the two weeks ending Saturday, Aug. 22, 1903:

Appel, Daniel M., major and surgeon, having completed the duty for which he was ordered to Denver, will proceed, at the proper time, to San Francisco and take transport to sail from that place not later than Oct. 1, 1903, for the Philippine Islands, where he will report for assignment to further duty.

Gregory, Junius C., first lieut. and asst.-surgeon, is relieved from duty at the U. S. General Hospital, Washington Barracks, to take effect at such time as in the opinion of the commanding officer of that hospital his services can be spared, and will then proceed to San Francisco and report for assignment to duty at the U. S. General Hospital, Presidio.

Godfrey Guy C., captain and asst.-surgeon, now at San Francisco, will proceed to Fort Apache for duty.

Godfrey, Guy C. M., captain and asst.-surgeon, is granted leave of absence for two months.

Hodson, F. A., contract surgeon, is granted leave for two months, to take effect on the arrival at Fort McKenzie of First Lieut. Henry H. Rutherford.

Johnson, Richard W., major and surgeon, is granted an extension of fifteen days' leave.

La Garde, Louis A., major and surgeon, is granted an extension of leave for three months.

Pomeroy, William, contract surgeon, is granted leave of absence for twenty days.

Sinks, E. D., contract surgeon, is granted leave of absence for two months from about September 1.

Wheeler, Lewis H., contract surgeon, is relieved from duty in the Department of Dakota, and will proceed to his home, Westport, Conn., for annulment of contract.

Brechemin, Louis, major, will proceed to Ord Barracks and report at that post for duty, to relieve Captain P. F. Straub, who, on being thus relieved, will proceed to Fort Leavenworth and report for duty.

Brechemin, Jr., Louis, first lieut., will proceed to Fort Baker and report for duty.

Carswell, R. L., first lieut., will report for transportation to the Philippine Islands and, on arrival at Manila, will report for assignment to duty.

De Witt, Wallace, first lieut., is relieved from duty at Fort Porter, and will proceed to Fort Myer for temporary duty.

Ford, J. H., first lieut., is granted a leave of absence for ten days.

Henderson, A. B., first lieut., is granted an extension of leave for twelve days.

Lyster, T. C., first lieut., will make not to exceed two visits each week to New York City on business pertaining to the examination of recruits.

Whitcomb, C. C., first lieut., is relieved from duty at Fort Preble and will proceed to Fort McKinley.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Aug. 22, 1903:

Surgeons A. G. Grunwell and W. H. Bucher, appointed surgeons from June 20, 1903.

P. A. Surgeon J. C. Thompson, commissioned as such Aug. 10, 1903.

Surgeon F. W. F. Wieber, ordered to the *Prairie* August 21.

Asst.-Surgeon R. E. Riggs, detached from the Naval Hospital, Philadelphia, and ordered to the Navy Yard, Washington, D. C.

Asst.-Surgeon H. L. Brown, detached from the Navy Yard, Washington, D. C., and ordered to the Naval Hospital, Philadelphia.

Surgeon H. G. Beyer, detached from the *Prairie* and ordered to duty as member of a Board on Barracks.

Asst.-Surgeon A. D. McLean, ordered to the *Wabash*, at Boston.

Asst.-Surgeon S. L. Scott, ordered to the Naval Hospital, Chelsea, Mass.

Asst.-Surgeon J. A. Randall, ordered to the Naval Hospital, Norfolk, Va.

Asst.-Surgeon F. G. Abeken, ordered to the Naval Hospital, New York.

Asst.-Surgeon T. N. Pease, ordered to the Naval Hospital, Newport, R. I.

Medical Inspector E. Z. Derr, detached from the *Chicago* and ordered home to wait orders.

Surgeon E. O. Huntington, when discharged from Naval Hospital, New York, granted sick leave for three months.

P. A. Surgeon D. H. Morgan, ordered before a retiring board, September 4, at the Navy Yard, Mare Island, Cal.

Asst.-Surgeon M. V. Stone, ordered to the Naval Hospital, New York, for treatment for a period of six months.

EYE COMPLICATIONS OF SMALLPOX.

SOME OBSERVATIONS DURING THE RECENT EPIDEMIC IN CLEVELAND.*

ALBERT RUFUS BAKER, M.D.

Professor of Ophthalmology and Otology of Cleveland College of Physicians and Surgeons; Oculist and Aurist of the Cleveland General and St. Alexis' Hospitals.

CLEVELAND, OHIO.

The recent epidemic of smallpox was the severest in the history of the city, and has seldom been equaled in the number of cases and in malignancy in recent times, in civilized countries, as will be seen by the accompanying chart, which shows cases and deaths, prepared by Dr. Probst, secretary of the Ohio State Board of Health. The total number of cases for 1902 was 1,248, with 224 deaths. The death rate was 17.9 per cent., and, as Dr. Probst well said: "This was the genuine old-fashioned smallpox." Many of the cases were of the most malignant character and exceedingly contagious, unlike the mild form of the disease which hitherto prevailed.

The cause of this widespread epidemic is not far to seek. During Dr. G. C. Ashmun's incumbency of the Cleveland health office, from 1880 to 1891, the rule requiring vaccination of all school children was rigidly enforced; but since that time it has been followed more in the breach than in its observance, consequently a large percentage of the population were unprotected by vaccination.

The general indifference to vaccination was fostered by a few cranks, led by a certain doctor of divinity, who organized an anti-vaccination society, and the vaporings of this crank and his followers were kept perennially before the public in the newspapers.

From 1898 to 1901, inclusive, an epidemic prevailed in Cleveland of a mild variola. In 1898 there were 48 cases and no deaths; 1899, 475 cases and 3 deaths; 1900, 993 cases and 16 deaths, and in 1901, from January 1 to August 23, 1,230 cases and 20 deaths, making a total of 2,746 cases and 39 deaths during the four years. The mortality was less than .015 per cent.

During all these years there was a constant clamor in the newspapers about the evils of vaccination. Unfortunately, during the summer of 1901 some poor virus was used, and many badly infected arms developed. Several cases of tetanus were reported. A particularly sad one was that of a beautiful young lady who died of tetanus from the result of vaccination performed by her brother, a young physician.

This epidemic was terminated by a vigorous policy of vaccination and quarantine by Dr. Heimlich, who occupied the position of health officer for a short time, but whose strenuous methods did not meet the approval of Mayor Tom Johnson (unfortunately, the mayor is immune, having had smallpox when a boy). On one occasion, it is alleged, he said that he did not believe in vaccination, and no member of his family should be vaccinated with his consent.

Dr. Heimlich was deposed, and Dr. Martin Fredrick installed as health officer. He immediately commenced a vigorous crusade of house-to-house disinfection with formaldehyd.

Dr. Fredrick is a most efficient officer, a thoroughly educated gentleman, an indefatigable worker, with great patience and perseverance. He had placed at his command every resource to combat an epidemic without vaccination. A more competent man for such an undertaking could not have been found, and his complete and disastrous failure ought to be sufficient to close the mouths of every anti-vaccinationist in the country.

There ought to be some way of disseminating this failure of Dr. Fredrick's disinfecting crusade in 1902 as wide as the reputed success of his efforts in 1901, which did not prove anything, as the epidemic had already been stamped out by vaccination before he assumed office. There was not a single case of smallpox in Cleveland when Dr. Fredrick took charge of the health office. The paper he read before the Academy of Medicine on "How We Rid Cleveland of Smallpox"[1] was unfortunate in its title, to say the least.

The antivaccinationists quoted him far and wide as being opposed to vaccination; but a careful perusal of his original paper reveals that he believes thoroughly in vaccination, and ought not to have been misrepresented. His protest was justly against the use of impure virus.

During the entire epidemic of mild smallpox, in which 2,746 cases were reported, not a single one of severe eye complications came under my observation, and I have not heard of any cases among my confrères.

During the recent epidemic there have been a number of cases of serious eye complications, and I wish to put on record the present condition of some of these unfortunate patients.

CASE 1.—Mr. O. N., age 30; superintendent. Large adherent corneal opacities of both eyes. Left eye light preception, but no hope of improvement. Right eye good light preception, a small band of clear cornea at outer side. It is possible but not probable that an iridectomy can be made at some future time, giving a little useful vision.

CASE 2.—Mrs. K. S., age 26; housewife. Large perforating ulcer of left eye, including entire cornea, followed by iridocyclitis. Enucleated to relieve pain.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

1. Cleveland Medical Journal, February, 1902.

CASE 3.—B. K., three-year-old girl. Large ulcer involving more than half of cornea of right eye. Staphyloma as large as a bean, with pressure bandage became smooth. Eye quiet, a little clear cornea above, but no useful vision.

CASE 4.—T. K.; laborer; age 33. Total staphyloma of cornea of right eye. Iridocyclitis. Enucleated to relieve pain.

CASE 5.—W. A. H.; mail clerk; age 27. Large ulcer of cornea of right eye including nearly entire cornea, but not perforated. Pupil moderately dilated. Hypopyon. Considerable pain. Ulcer healed very slowly. Counts fingers, but can not hope for much improvement.

CASE 6.—E. P., school girl; age 12. Small ulcer of cornea of right eye. Made little complaint of eye until after discharged from hospital. Several days afterward suddenly developed intense panophthalmitis. Phthisis bulbi.

CASE 7.—G. S., school boy; age 10. Ulcer of cornea of left eye. Panophthalmitis developed before discharged from hospital. Phthisis bulbi.

CASE 8.—J. L., age 27; bricklayer. Left eye ulceration of entire cornea. Immense staphyloma developed so that lids could not be closed and became painful. Enucleated.

Right eye ulceration of almost entire cornea. Anterior chamber full of pus. Saemich operation. Fistula of cornea. Still under observation. Small portion of clear cornea. May be able to make iridectomy and secure a little useful vision, but very doubtful.

CASE 9.—R. F., bookkeeper; age 28. Large ulcer of cornea of right eye. Not perforated. Opacity of cornea at present time, including lower 2/3 of cornea. With pupil dilated, vision 10/200.

CASE 10.—T. R., driver of delivery wagon; aged 19. Ulcer of lower half of cornea of right eye not perforated. Vision six months later 20/200.

CASE 11.—F. M., press hand; age 23. Large perforating corneal ulcer of right eye. Discharged from hospital Nov. 1, 1902. At present writing, March 26, 1903, adherent scar involving at least 3/4 of the cornea, with small fistula just above where the pupil ought to be. Light perception. Still under treatment.

CASE 12.—B. M., four-year-old girl. Discharged from hospital with small corneal ulcer of right eye. Subsequently developed panophthalmitis. Phthisis bulbi.

The following notes were made by Dr. Hartzell. The patients have not been seen since discharged from hospital.

CASE 13.—John S., age 26. Discharged from hospital with panophthalmitis of left eye.

CASE 14.—Mary P., age 6 months. Discharged from hospital with small corneal ulcer of left eye.

CASE 15.—Henry B., age 44. Left hospital with small ulcer of left eye.

CASE 16.—Louis A., aged 2 years. Discharged from hospital with small ulcer of left eye.

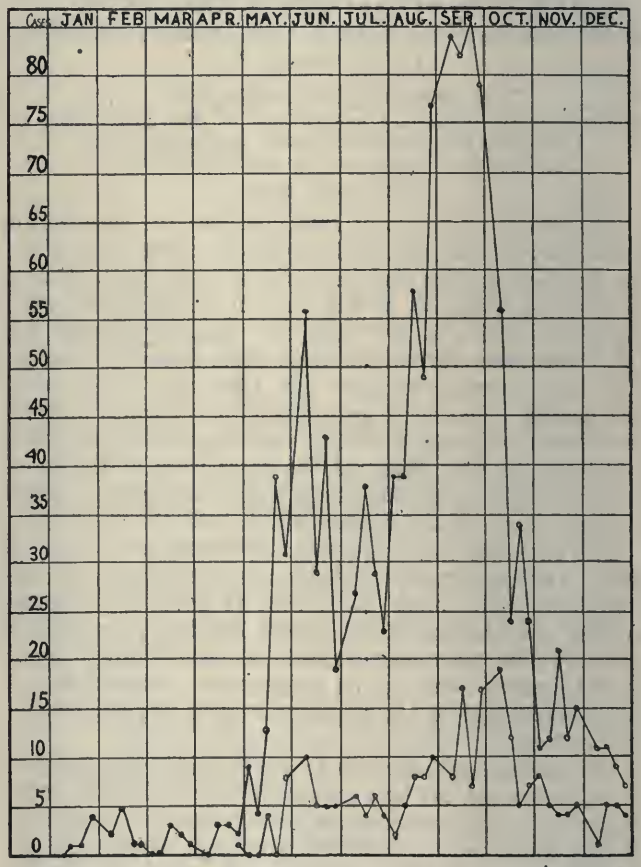
CASE 17.—Jennie J., age 28. Discharged from hospital with large ulcer including entire cornea of left eye, and almost entire cornea of right.

CASE 18.—William B., age 18. Discharged from hospital with small ulcer of cornea of left eye.

CASE 19.—Gilbert B., age 30. Discharged from hospital with perforated corneal ulcer and iridocyclitis of left eye.

CASE 20.—Benjamin C., age 55. Discharged from hospital with panophthalmitis of right eye.

CASE 21.—Sadie G., age 30. Discharged from hospital with small ulcer and iridocyclitis of left eye.



CASE 22.—Frank B., age 24. Discharged from hospital with small ulcer of right eye.

CASE 23.—Walter V., age 18. Discharged from hospital with large ulcer of cornea of right eye and severe ulcer and iridocyclitis of left eye.

No records are available to determine accurately the total number of cases in which the eyes were seriously involved. But I requested Dr. Homer J. Hartzell to make a note of the cases that came under his service at the Detention Hospital. Dr. Hartzell admitted and treated 425 cases. He had 16 cases of late eye involvements, 13 of one eye and 3 of both, or about 3¾ per cent., which would give us between 45 and 50 cases during the entire epidemic. I think this is approximately correct.

The severity of this infective process may be better appreciated when we recall that of the above 23 cases, 4 are blind in both eyes, with little hope of improvement; 8 have either been enucleated or atrophied from panophthalmitis; 6 are blind in one eye, but the form of the eyeball is preserved. It is probable that several of these will have to be enucleated later. Three have vision of less than 20/200, and not more than 5 have vision better than 20/200, and 2 have corneal fistula, and are still under observation.

In view of this discouraging array of blind and damaged eyes, notwithstanding our supposedly newer and

Smallpox in Cleveland, 1902. Upper curve, cases; lower curve, deaths.

better methods of treatment, we can readily believe the statement of the older writers, that one-third of all the blind people in Europe before Jenner introduced vaccination were due to smallpox.

All these patients had severe confluent variola. In not a single case could be elicited a history of having been successfully vaccinated. In all of the cases attention was called to the corneal lesion relatively late in the disease, about the end of the second, or beginning of the third week, and in a few cases much later. Case 12 was discharged from the hospital with a small ulcer of the cornea, but three weeks later panophthalmitis developed.

A number of these cases were examined bacteriologically and streptococci were always found. Occasionally a mixed infection, with staphylococcus, was present.

Most severe cases of variola have a conjunctivitis and great swelling of the lids early in the disease, and fre-

quently it is impossible to open the eye so as to see the cornea for several days. The fear that destructive corneal lesions may be transpiring unobserved beneath the greatly swollen lids is not often realized; for when the lids can be first opened the cornea will be found clear. The first indication of corneal complications will usually be noticed several days later, after pus and crusts have been forming, and it is quite certain the infection is carried into the eye from the skin on the fingers, handkerchief, dressing, eyedroppers, or directly from crusts on the edges of the lids.

When the house physicians, nurses, attendants and patients at the detention hospital became fully cognizant of the importance of this observation as to the source of the infection, and every possible precaution was taken to disinfect the structures around the eye, there was an appreciable falling off in the number of eye complications.

The patients, however, who suffered most severely were those who barely escaped with their lives, and, doubtless, one reason there are not more blind from smallpox is because so many of the confluent cases die. The vitality of those who survive is so lowered that the cornea sometimes melts away with very little attempt at repair, as I have sometimes seen it do in severe cases of scarlatina, typhoid fever, and other severe and depressing diseases.

In view of my observations during this epidemic, I can not agree with Mackenzie's[2] statement: "Secondary variolous ophthalmia seldom leads to destruction of the cornea unless the case is altogether neglected." Our cases were not neglected. Resident physicians were in constant attendance, the best of trained nurses were employed, oculists were frequently consulted and patients were given constant and careful attention. One of the resident physicians said: "More time and care was devoted to the eye cases than all the others combined."

Doubtless, there were mild cases of keratitis that escaped our notice, such as described by Dr. Edward Jackson[3] in his admirable paper. But they must have been rare. No case of primary infection of the conjunctiva, such as reported by Dr. E. P. Morrow,[4] came under our observation. I am indebted to Dr. D. B. Smith for the report of the following case: Miss C. K., nurse at the detention hospital, was vaccinated a few days before taking the position, and had a very much inflamed arm, with several characteristic pustules. On the mucous membrane of the right upper eyelid, just at the transitional portion, a perfectly well-defined ulcer appeared. The lid was swollen greatly, and the diagnosis of vaccine pustule was made. Patient made a perfect and uneventful recovery. All of the cases began relatively late in the disease, and were due to a secondary infection, although it is quite possible that there may have been some slight abrasion of the cornea as the result of a primary lesion, thereby permitting the entrance of pathogenic germs later.

Early in the epidemic, while laboring under the belief that the eyes were destroyed as the result of a primary lesion of the conjunctiva or cornea, cases were treated with instillations of 1 per cent. solution of nitrate of silver as a prophylactic, but it seemed with deleterious results. Then protargol formalin and other disinfectants were used, with no better success. Later, subconjunctival injections of bichlorid were used in several cases without benefit. Fewer cases of corneal complications developed, and our cases progressed better when a routine practice was adopted of frequent washing of the face and lids with 1/4000 bichlorid and flooding the conjunctiva four or five times daily with saturated boric acid solution, and on the first evidence of corneal complications an instillation of 1 per cent. of atropia sulphate two or three times daily. The later treatment of these cases was in no way different than that of corneal ulcers from any other cause.

In conclusion, I wish to observe:

1. In view of the growing sentiment against vaccination almost any community is liable to experience an epidemic as disastrous as that through which Cleveland has just passed.

2. The eye complications of smallpox are greatly to be feared. The dangerous corneal complication is a secondary infection, commencing about the twelfth day, but many come much later.

3. The infection in the Cleveland epidemic was a streptococcus one, and different in no way from similar infection of the eyes of a patient already much exhausted from a serious disease.

4. No specific prophylactic treatment has been found, and the best that can be done is to keep the face and eyes in as nearly an aseptic condition as possible by frequent washing and the use of such antiseptics as will prove the least harmful to the eye.

DISCUSSION.

DR. J. F. FULTON, St. Paul, Minn.—I did not know until a recent epidemic that the eye complications of smallpox were so common. During a recent epidemic we had the same fight in our legislature for the enforcement of vaccination. I had under my care two cases of central ulceration of the cornea. They occurred during the stage of convalescence and resulted in permanent opacities, and it will be necessary to do an iridectomy to secure an improved vision. They were treated on the same line as we treat all ulcers of the cornea. There is a question as to the nature of the ulcer—whether it is the eruption of smallpox or an ulcer due to the run-down condition of the system. It is quite possible that it may be the same eruption as that on the skin.

DR. LEARTUS CONNOR, Detroit—It is a question whether the eye complications were due to the general eruption or to streptococcic infection. It would seem in these cases that it was due to the infection, and if so, measures can be taken to prevent it. We have had some mild cases in Detroit, but I have not heard of an eye being lost from this cause. It may be due to the fact that at periodical intervals the whole city has been thoroughly vaccinated. We have lately been made to believe that this was illegal, but formerly it was not considered so, and general vaccination prevented an epidemic. I am convinced that in this, as in allied diseases, we shall fail of best results until we teach the people that vaccination is absolutely necessary. Dr. Baker's observations increase the force of our argument. If we can show that even though the lives of patients are saved, they may be blind, or partially so, we may be able to get the laity to listen to us. The only thing we can do is to promote organization and teach the people such facts as these presented to-day. How much the discovery of the smallpox organism by Dr. Councilman will affect this matter is still undetermined.

DR. B. H. MANN, Texarkana, Ark.—I have treated perhaps five or six cases of corneal ulcer following smallpox, with loss of eye in two cases. Treatment seemed to have no effect whatever.

DR. JOHN A. DONOVAN, Butte, Mont.—As to the question of primary or secondary infection being cause of ulcers, in an extensive epidemic two years ago I saw some cases where primary eruptions occurred on the cornea simultaneously with the skin. These all healed readily when treated with boracic acid wash and yellow oxid ointment. These severe ulcers with

iritis, etc., I treated were all due to secondary infection. Light cautery punctures in the margin of healthy tissue around the ulcer is the most efficient treatment.

DR. R. W. MILLER, Los Angeles, Cal.—The statistics are indeed instructive, and come to us with a great deal of force. They have the merit of freshness, and may be more helpful to us in bringing the laity to a realization of the dangers of smallpox and the benefits of vaccination than the older statistics. We have to go back but a few years in order to obtain abundant statistics which should convince anybody. In spite of this, however, we find people opposing vaccination. In Los Angeles a few years ago mass meetings were held by antivaccinationists opposing vaccination, and these meetings were headed by the editor of one of the daily papers, who refused to have his own child vaccinated so that it might continue to attend the public school.

As suggested by Dr. Connor, we may hope for better things when the profession is more thoroughly organized. The adoption of suitable resolutions and the bringing to bear of concerted influence on the legislatures and health boards will enable us to accomplish more than we have done in the past. There is no question as to the growing sentiment against vaccination in this country, and the only thing perhaps that will convince the public will be a fearful epidemic of smallpox.

I have seen but few of these cases, but I think with Dr. Donovan, that if the ulcer is limited, the cautery is the best means of treatment. As to the applications of medicines, we can often accomplish more by frequent cleansing with the milder agents than by the more irritating agents.

DR. OSCAR DODD, Chicago—I have seen several cases in Chicago at a late stage, after the corneal lesions had healed. Our cases were very mild. I would like to ask Dr. Baker if the corneal complications came on during the stage of eruption or are a later infection.

DR. E. P. MORROW, Canton, Ohio—Dr. Baker mentions a case that occurred in my practice.[1] The eye trouble occurred before the general eruption occurred, and I look on it as the inoculation lesion of smallpox. The patient, about two weeks before, had slept with his cousin, who was supposed to have chicken-pox. The next day in shaving himself he used the same mug his cousin used, and probably got some lather into the eye. Seven days before the general eruption occurred he presented himself with a slight conjunctival hyperemia, limited almost entirely to the lower half of the eyeball. There was a decided white spot, 3 mm. in diameter, on the hyperemic area between the corneal limbus and the caruncle, and in the center of this spot a distinct black dot. I sent him home, assuming the trouble to be insignificant. The next day he presented himself with greatly swollen lids, having the appearance of a case of purulent conjunctivitis; on separating the lids, however, there was no discharge. There was, however, a subconjunctival swelling in the lower half of the bulbar conjunctiva, while the upper half of the cornea and conjunctiva were not involved at all. Until the end of the case there was no discharge. On the seventh day he had a general eruption, which proved to be smallpox. The eye went on to recovery, although there was a slight involvement of the cornea. There was haziness of the lower portion of the cornea, but under irrigations with boracic acid and the use of hot fomentations the eye recovered without any serious damage. I believe this to be a case where the conjunctiva was the initial point of inoculation of smallpox.

DR. D. A. THOMPSON, Indianapolis—During the past year we have had a siege of smallpox, and I saw a number of conjunctival cases, one a severe episcleritis. In the confluent form there were ten cases of ulcer, of which four were lost. It was demonstrated in our cases that vaccination plays an important part in mitigating the trouble.

DR. ALLEN GREENWOOD, Boston—It is reasonable to expect that Dr. Councilman's discovery will bring about a new method of treatment, and that we may possibly be able to control this condition as we do the diphtheritic conjunctivitis by an antitoxin.

1. Ophthalmic Record, July, 1902.

DR. F. W. HILSCHER, Spokane, Wash.—I would like to report a case similar to that of Dr. Morrow's, in which there was conjunctivitis near the limbus before the eruption of the disease appeared. I treated the patient about a week before the eruption broke out. It had the appearance of a phlyctenular conjunctivitis. At the end of about a week he seemed depressed and had a little fever and general malaise, and I suspected smallpox, and called in a health officer and turned the patient over to him. It illustrates also the value of isolation. The patient was from just outside the city limits. We had an efficient city official, but a rather negligent county physician; the city remained comparatively free from the disease, and the cases in the city could be traced in nearly every instance to infection from the county outside the city limits.

DR. JOHN E. WEEKS, New York—The discussion has brought out that the affection may sometimes be primary in the eye. I had thought that perhaps in all the cases the infection was a secondary one, and due to the entrance of substances from the lids or brow after abrasion of the corneal epithelium. I have not had experience in the treatment of smallpox, but it seems to me that the use of oily preparations to prevent the scattering of the exfoliations would be of service in preventing secondary infection of the eye; oily preparations, with perhaps an antiseptic added. In regard to the complications that may follow, I have seen cataract as a result of corneal ulcer following smallpox.

DR. ALBERT R. BAKER, Cleveland, Ohio—I believe in all cases the eruption appears on the mucous membrane just as on the skin, and probably in all there was a primary eruption of the mucous membrane of the eye. The eye is so greatly swollen in confluent cases that it is difficult to tell. It is impossible to open the eye to examine it for several days. But for all practical purposes these cases of bad infection are secondary, and the infection is conveyed to the eye by means of the fingers, or in some similar way. We used vaselin, as suggested by the Chairman, in all these cases. As to the primary infection as in Dr. Morrow's case, the only one that in any way resembled that was the case of Dr. Smith, in which there was a vaccine infection carried from the arm to the eye.

The general condition of these eye patients was pitiable indeed. Even with good nursing in many of them you could pick up the crusts from the bed in handfuls weeks and months after the case was discharged from the hospital as cured.

As to the chart, you will observe that it keeps running up gradually until we were having 85 to 88 new cases reported a week, with 15 to 20 deaths. Our health officer was still disinfecting. We were threatened by quarantine by all lake cities, and then our business men became alarmed and called in the State Board of Health, who insisted on general vaccination, appointed 250 public vaccinators and vaccinated over two hundred thousand people within a week, and the epidemic was almost immediately ended, as shown by the chart.

CRAMP OF THE CILIARY MUSCLE DUE TO EYESTRAIN.*

JOHN W. WRIGHT, M.D.
Professor of Ophthalmology in the Ohio Medical University; Ophthalmologist to the Protestant Hospital.
COLUMBUS, OHIO.

As every physician should have a knowledge of what is known as professional cramp, a painful spasm of the finger, hand, forearm or arm from excessive use, as is often found in writers, telegraphers, pianists, violinists, typewriters, etc., so should every oculist have a knowledge that certain eye muscles, especially the ciliary, are liable to the same condition when subject to enforced contraction for prolonged periods of time.

No oculist who does much fitting for glasses has failed to notice that, although the greatest care has been ob-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

served in this part of his service, occasionally he will meet a case where it is impossible to obtain satisfactory results and relieve the annoying nervous symptoms that usually accompany refractive error, although under the effects of a cycloplegic the very best possible vision has been obtained. Such patients are usually between the ages of 25 and 40 years, although cases much younger are occasionally encountered.

When the patient returns to us with the complaint that he is not relieved of his headaches or whatever nervous head symptoms may have been attributed to eyestrain, and that his vision has not been improved, we apprehend that a too high or a too low correction may have been made, or that there may have been a slight deviation from the exact angle in the correcting cylinder for the astigmatism, all of which has been carefully gone over, and allowances made from time to time, without appreciable benefit to the patient.

Should the patient have been long a sufferer from the headaches and eye pains which are usual in refractive errors, especially if there is an astigmatism, the correcting lenses may have relieved him for a short time, to some extent, but not entirely, and many of the old annoying symptoms return, although perhaps in a mitigated form. This condition is known as ciliary cramp.

THE CAUSES OF CILIARY CRAMP.

1. An emmetropic eye may have cramp of its ciliary muscle. Too much near-work leads to it. Impairment of the general health will augment it, but the cramp may exist in an emmetropic eye when there is good health from too much near-work.

2. The ametropia conduces to it, especially hyperopia and astigmatism, whether hyperopic or myopic. In mixed astigmatism there is great predisposition to the cramp with a tendency to headaches and eye pains. This may be attributed to the unequal contraction of the sphincter fibers in order to obtain a clear retinal image.

It is well understood that accommodation depends on the contraction of the circular fibers of the ciliary muscle and the elasticity of the crystalline lens. When there is normal refraction of the eye and but an ordinary amount of work for the muscle to perform, and the patient is in fair health and is not suffering from some affection that would impair the general muscular tonicity, the eye performs its functions instinctively—not reluctantly—but with a natural impulse and without effort. If, however, there is an excessive amount of near-work to perform, or there is general impairment of muscular tonicity, although the refraction may be normal or made so by correcting lenses, the ciliary muscle is liable to become cramped from the excessive effort to contract.

If the eye is hyperopic or astigmatic, with these conditions existing, then the ciliary muscle must become inordinately contracted in its effort to perform but an ordinary amount of work. If the eye is myopic and uncorrected, the ciliary muscle, not being called on to perform much service for near-work, soon loses its tonicity for want of action; for this reason should an exigency require that the myopia be corrected to facilitate distant vision, the patient is unable to accommodate for near-work, or if so, very reluctantly and ineffectively. The weakened condition of the muscle, rendered so for want of use, readily conduces to cramp.

In high degrees of uncomplicated and uncorrected myopia there can not be cramp of the ciliary muscle, but it is found in low degrees of this refractive condition and in high degrees, where full, or quite full, correcting glasses are in use. If myopia is corrected early, the ciliary muscle may regain its normal functions, and is then liable to become cramped from overwork, as does that of the emmetropic eye.

I anticipate the fact that there are those who are skeptical with regard to ciliary cramp. They term it hypertrophy of the ciliary muscle. I believe there is hypertrophy of the ciliary muscle, but it is readily diagnosed from cramp.

When there is cramp of the ciliary muscle it is temporarily relaxed by the use of a cycloplegic, and if the patient is subject to headache, due to eyestrain, it is relieved as soon as the cycloplegic has relaxed the accommodation. We have all had patients who were suffering from headache at the time they consulted us, who, as soon as their eyes were placed under the effects of a cycloplegic, found that their headache had entirely disappeared.

In hypertrophy of the ciliary muscle there is no strain and consequently no cramp, for the muscle has become permanently fixed, and, therefore, ineffective as far as contraction and relaxation are concerned. The patient with hypertrophy of the ciliary muscle can usually see well for near-work, because the muscle has become permanently contracted and is fixed for near-work only, but can not see well for distance, and because of the permanent convexity of the lens is practically myopic, and for distance requires a concave lens to make perfect vision. When the muscle becomes hypertrophied and the lens permanently fixed for near-work, the range of accommodation is necessarily very limited, and the patient has passed the point where he suffers from cramp.

I can conceive a hypertrophied condition of the ciliary muscle where the sphincter and radiating fibers may be increased in size and strength and their functions still maintained, to attain which would require a systematic exercise of both sets of fibers, which no ordinary avocation could possibly accomplish.

The cramp of a muscle is an evidence of its weakness. When a muscle is compelled to remain in a fixed position for long periods of time, it becomes weak, simply from the exertion necessary to maintain this fixed position, whether it has been held there by mechanical means, as to allow a fractured bone to unite, or voluntarily, as with the contracting fibers of the ciliary muscle in the act of near-seeing. After the protracted contraction of a muscle, the tendency is to keep more or less contracted, and when through necessity it must relax, pain accompanies the effort.

Cramp of the ciliary muscle is not constant, although the conditions which produce it may be present. As before stated, it may occur in an eye whose refraction is normal, simply because the eye is overworked. One of the first symptoms of ciliary cramp, aside from headache and pain in the eye itself, is that vision for distance is variable. At times the patient may have good distant vision, but on the least exertion at near-work the cramp returns with great severity, and the patient suffers accordingly. It is this tendency of the ciliary muscle to return to its old condition of contracting that gives the oculist so much concern after he has properly fitted his patient with glasses.

TREATMENT.

The treatment which has been most successful with me in cases of ciliary cramp consists of cycloplegics, and for several reasons I believe that those whose effects are transient are much better than those whose effects are prolonged, like from atropin. The first reason is that most patients are compelled to continue

regularly their daily avocations. The second reason is that prolonged relaxation of the muscle is injurious, because long-continued inaction of the muscle will, of itself, have a tendency to weaken it, in which condition it will readily cramp again if the patient is compelled to use the eyes for enforced near-work.

As a transient cycloplegic, and one, too, which will effect thorough relaxation of the accommodation, I am partial to a combination of equal parts of a 1 per cent. solution of homatropin and a 2 per cent. solution of cocain. The cocain seems to augment the effects of the homatropin, besides, its analgesic effects have a special bearing with patients who suffer much, as many do, from the pain attending ciliary cramp.

To relax the accommodation preparatory to fitting for glasses I instill one drop of the above solution in the eyes every ten minutes until five applications have been made. In ten minutes after the last application the accommodation is usually relaxed to its utmost extent, when the fitting may be proceeded with, which must be concluded within two hours, for at the end of this time the cycloplegia usually begins to pass off.

To relieve ciliary cramp, I instill one drop of this solution into each eye on retiring for the night. The patient is usually able to attend his work, whatever it may be, the next morning, should he retire at a seasonable hour. It requires about ten hours for the cycloplegia to pass off, when the muscle will usually be able to perform its functions readily.

I prescribe this remedy daily, at the time indicated, whenever and as long as there is evidence of cramp. Frequently but one eye is affected, when it can be treated alone. My rule is to use the remedy on retiring, only when the patient has suffered during the day, and with those only whose eyes are emmetropic or made so by correcting lenses under the effects of a cycloplegic.

Gelsemium has an excellent effect on ciliary cramp. This drug was brought to my attention by a physician, who referred to me a lady who had been a great sufferer from hemicrania, due to eyestrain, and whom I fitted for glasses. Although the patient was greatly relieved, she still suffered occasionally from headaches, especially after the eyes had been used for a long period at near-work. For this the physician gave her the following prescription, which gave her immediate and permanent relief, although she had taken the same prescription before she was fitted with glasses with only transient effects. It was a favorite prescription with him for headaches:

℞. Morphia sulph. .....gr. i | 065
Liquor potassi arsenitis.
Tinct. gelsemium (green root), āā.....ʒi 4 |
Elixir simp., q. s. ad.....ʒiv 120 |

M. Sig.: One teaspoonful every six hours until headache ceases.

I prescribe his remedy in persistent headaches and eye pains only, and then only in connection with the cycloplegic, as previously indicated, and that after the cycloplegic has failed to give permanent relief.

The physician always insisted on the green root tincture, and not without cause, for I have found that the tincture of this root of the shops is usually worthless. I have prescribed the gelsemium alone, but never with the satisfactory results as in the combination given.

Knowing the therapeutic effects of morphia and arsenic in a general way, we readily comprehend their effects in spasm of muscular tissue; but of gelsemium I would say that it has a specific effect on cyclospasm that is worthy the considerate attention of every oculist.

DISCUSSION.

DR. EDW. JACKSON, Denver—We are too apt to feel that the only question to be settled is whether there exists a spasm of accommodation and its amount. It will be productive of a better knowledge of the subject if we go a little deeper into these cases. There are totally different conditions capable of yielding the same alteration of refraction. There may be, and probably is, a condition of surplus accommodative power in some young hyperopic eyes that is quite removed from spasm of accommodation from overwork. To consider them the same thing is preventive of our clearly understanding these conditions or treating them properly. We can recognize these and also a third form of spasm that is closely dependent on abnormal conditions of the central nervous system.

The next point is the idea widely held that in very high myopia there is no strain on the accommodation. I do not believe this is correct. The high myope, as a matter of fact, often has the thing he is looking at within his far point, and is straining his accommodation. In reading he must sometimes vary his accommodation 2 or 3 diopters to read lines of ordinary length. High myopia with binocular vision almost constantly entails strain of accommodation. The myopia is seldom equal in the two eyes.

As to the treatment, the important thing is the discovery and removal of the cause, which is generally some uncorrected ametropia or some overwork of the eyes. When that has been thoroughly attended to, in patients of good general health, the condition quickly passes away.

I have used cycloplegics in the way mentioned to some extent, but would be very much afraid of using a 1 per cent. solution of homatropin at night if I expected the patient to use the eyes the next day. I have used a 1/5 per cent. solution, and with some satisfaction; also a solution of euphthalmin, which produces a tendency to relaxation. Recovery from the euphthalmin is complete in ten or twelve hours.

DR. JOHN A. DONOVAN, Butte, Mont.—In reference to the treatment of this condition, I have found homatropin to be more or less unreliable. I believe the nearest thing to a total cycloplegic in this trouble is the hydrobromate of hyoscin. My attention was called to it by Dr. Chas. Baker some years ago, and I am convinced that it is considerably the stronger and decidedly more reliable. Towards the end of the week these patients suffer most, and if they use it on Saturday night, by Monday they are able to work again; it takes three or four days to fully pass off.

DR. LAWRENCE R. RYAN, Galesburg, Ill.—In regard to the prescription of Dr. Wright's, containing gelsemium, he made the statement that he was never able to get relaxation of the spasm by the use of gelsemium alone. That would seem to militate against its use. It would seem to me that the morphia itself would relieve the spasm quicker than the gelsemium.

DR. J. W. WRIGHT, Columbus, Ohio—In regard to the use of the solution of homatropin and cocain, when it is used to produce cycloplegia, if instilled four or five times it does not pass off in twenty-four hours, but if only used once, on retiring, it passes off by the next morning.

Knife and Fork Surgery.—The *Hospital* discusses Koenig's method of operating without ever touching the tissues, much as we eat our meals by aid of forks and spoons instead of clawing our food. By practice with suitably-devised metal instruments, Koenig of Berlin has found that he can get through many operations without ever touching the wound. Even in abdominal cases, in many of which it is often impossible to avoid introducing the hand, he carries his instrumental method to its extremest limit. In operating on cases of appendicitis during the quiescent interval he has been able to do the entire operation with instruments. The surgeon often does things with his fingers which, by aid of a little practice, could be done just as well with an instrument, and, if we are to accept as correct all that is said about hand-infection, it would often be well, in suitable cases, to adopt the "knife-and-fork" method.

OCCURRENCE OF THE STRONGYLOIDES INTESTINALIS IN THE UNITED STATES.*

MARSHALL LANGTON PRICE, M.D.
BALTIMORE.

I present for your consideration a somewhat brief and imperfect account of one of the rarer nematodes; rare, at least in this climate and latitude, though occurring with considerable frequency in tropical and sub-tropical countries. I refer to the *Strongyloides intestinalis*. The parasite is endemic in Cochin China, where it occurs in association with the diarrhea peculiar to the country—hence the name bestowed on it by European physicians, "Cochin China diarrhea."

This animal forms one of the class of parasites whose pathologic action is limited to the intestinal canal, and does not extend, as does that of the *Amœba coli*, to the liver and other organs. Teissier has claimed to have observed rhabditiform embryos circulating in the blood, and to have produced metastatic foci in the lungs of infected frogs. These observations, however, have not been confirmed by any other observer, and, for the present, we must conclude that the parasite's pathologic influence is limited to the gastrointestinal tract. The consideration of the diseases caused by animal parasites, particularly those infecting the intestinal canal, is especially opportune at this time, as the different varieties of acute and chronic diarrheas and dysenteries are only now beginning to emerge from the obscurity which has previously enveloped them, and are being placed on a rational basis, where the knowledge of them previously was wholly crude and empirical. This knowledge has already borne valuable fruit; you are familiar with the work recently done under the direction of Professor Welch, of Baltimore, in the investigation of the summer diarrheas of infants, of the discovery of the essential cause, and of the preparation of a serum which promises a specific against a disease causing more than one-half the mortality in urban communities during the summer months.

It is only in the last decade that we have begun to realize that many cases of chronic intestinal flux in this latitude are due to the *Amœba coli*, and one form of parasite which we previously considered wholly indigenous to the tropics, has thus been given a wide sphere of activity in the diseases of temperate climates. We have later been able to recognize the cause of another class of diarrheas through the discovery by Shiga and Flexner of the *Bacillus dysenterica*, and it is probable that many other tropical parasites will be found to be the pathogenic factors of our native diseases. The rôle played by the strongyloides genus in diseases of the United States is hard to ascertain at the present time, but I do not believe it will ever be a prominent one in this climate, yet it will take a place as an etiologic factor in many individual instances in which the nature of the disease was previously unrecognized. The occurrence of the *Strongyloides intestinalis* in the United States was first reported by Thayer[1] from three cases occurring at the Johns Hopkins Hospital, Baltimore, his work remaining the best monograph published on the subject in the United States.

A short résumé of the history of the parasite may here be of interest:

In 1876, Normand, a medical officer of the French navy, while investigating the diarrhea among French troops returning from China, discovered this parasite in the stools. It was studied by Bavey in the same year, and the latter named it *Anguillula stercoralis*, in analogy with the similar terrestial anguillula *Rhabditis terricola*, genus leptodera. The parasite is found constantly in the stools of these patients, and Bavey and Normand considered it the probable cause of Cochin China diarrhea. When these stools were kept warm for four or five days, sexual development took place, some of the parasites assuming the male and some the female type—the original first observed being, indeed, only an embryo. The following is Bavey's description of the sexually mature forms:

> The length of the female is about 1 mm. fully grown, the breadth about 0.04 mm., body cylindrical, slightly diminishing in size anteriorly and tapering to a sharp point posteriorly. When the worm retracted forcibly, slight transverse furrows were to be seen. The mouth possessed three distinct lips and was continuous with the triangular esophagus, which after a stricture dilated again to a second ovoid enlargement. The intestine which followed was fairly visible and ended in a little protrusion on one side of the body near the base of the tail. The intestine was pushed slightly aside by the uterus. A little below the middle of the body on the ventral side opened the vulva leading to the uterus, which extended from the intestinal ventricle to a point near the intestinal opening; here the eggs were massed in varying numbers. In some instances the young had actually broken the shells and were free in the uterus, though more often the eggs on deposition contain well-formed motile embryos.
>
> The male is about 1/5 smaller than the female; the perintestinal cells are more clearly outlined and were accompanied by another long gland, which seemed to consist of small rounded globules. This organ, doubtless the testicle, entered the base of the tail in two small horn-like spicules with tapering extremities curved inward; these spicules contained canals . . . coiled in the same direction . . . and were twice as short.

In the following year a complication occurred in the history of the parasite, with the discovery by Normand of a nematode in the small intestines of a patient dead of Cochin China diarrhea. This was similar to the parasite found in the stool, but larger than even the sexually differentiated forms, and possessing other structural differences. Bavey was able to obtain it from several successive autopsies following death from this cause. He considered it a distinct species, which he called the *Anguillula intestinalis*. It was found only in the female form and was described as follows:

> Length 2.20 mm., average breadth 0.03 mm., the body little tapering anteriorly, terminated rather suddenly posteriorly in a conical tail, the extremity of which appeared rounded and even a trifle dilated . . . . the surface showed a delicate transverse striation; the mouth . . showed three small lips. It opened into an esophagus, practically cylindrical, which occupied about ¼ of the length of the animal, and showed neither swellings nor striations; it was followed by an intestine with which it might readily be confounded without a marked change of color. This extended almost to posterior extremity of the body, but it ceased to be visible in the middle part, which was occupied by a very large elongated ovary. The vulva was situated in the posterior third of the animal and in its neighborhood the uterus contained five or six elongated eggs . . the eggs and viscera were of a yellowish green color and rather opaque and apparently finely granular.

The parasitic form is found at autopsy in the small intestine. They are abundant in the duodenum, less numerous in the jejunum, and absent in the ileum. They seldom reach the stomach under normal conditions, but have been found in the vomitus after an emetic. In

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

1. Journal of Experimental Medicine, vol. vi, No. 1, Nov. 29, 1901.

stools which have been kept warm for a varying period there is another embryonic form which is frequently seen; this is a much longer, thinner embryo of a more homogeneous constitution, and more actively motile than the more common rhabditiform embryo. This represents the strongyloid form in the embryonic state. The parthenogenetic female shows also the strongyloid type, and indeed, probably develops directly from the strongyloid embryo. The strongyloid embryo, although longer than the rhabditiform, never attains the size of the parthenogenetic mother worm; the average length is from 0.4 to 0.5 mm., the greatest length being 0.7 mm., while the parthenogenetic worm averages 2.20 mm. The following is a comparison of the size of the different varieties:

	Rhabditiform.	Filariform.	Free Sexually.	Partho-genetic, M. W.
Length	0.33 mm.	0.50 mm.	1. mm.	2.20 mm.
Breadth	0.022 mm.	0.02 mm.	0.04 mm.	0.03 mm.

The eggs are oval, and resemble uncinaria eggs, and measure 60 to 70 microns by 34 to 39 microns.

Following Normand's original investigations of the parasite as occurring in Cochin China, other observations were made on the parasite in the tropics. Laveran, Liebermann, Roux and Chartaing each reported cases in 1877 and 1878. Chauvin reported a case originating on the Island of Martinique. Grassi, in 1879, studied the worm, and placed it in a species which he called strongyloides, closely allied to the genus strongylus, of which the most important member pathologically is the uncinaria, or *Strongylus duodenale,* or, as it is called in Europe, *Anchylostoma duodenale,* from which it differs morphologically by certain structural peculiarities, and pathologically by important differences which will be described later. In 1880 the parasite first appeared in Europe with the report by Perroncito of its discovery in the intestinal tract of laborers in St. Gothard tunnel, in whom it occurred in association with the *Anchylostoma duodenale* in certain grave anemias described by Perroncito at that time; since then sporadic cases have been reported from Brazil, Russia, Sicily, Italy, Dutch Indies and Egypt. In 1899 cases were reported along the Rhine and in East Prussia. In 1901 Strong described cases occurring in the Philippine Islands.

In order to understand the divergent opinions that have been held in regard to the unity or heterogenicity of these nematodes it is necessary to describe the forms of parasites that may be found in the alvine discharges of the patients suffering from Cochin China diarrhea during life, or in their intestinal canal after death, all of which are now believed by the preponderance of observers to be morphologic variations of the same parasite. These are, briefly:

1. The rhabditiform embryo *Anguillula stercoralis,* found in the stools on immediate examination.

2. Filariform embryos usually found alone in the stools after one or two days, replacing the rhabditiform embryos.

3. The sexually differentiated form, *Rhabditis stercoralis,* occasionally found in the stools after a varying period—usually about five days.

4. The parthenogenetic mother worm, *Anguillula intestinalis,* found in the intestinal canal of the host at autopsy.

It appears that the worm shows a different development here from that which it exhibits in the tropics. The development of the sexually differentiated living generation must be regarded as the highest exponent of the parasite. This manner of development appears to occur only rarely in temperate zones, and in these regions we must consider that some conditions are less favorable to the parasite's attainment of the highest form, the difference lying either in intrinsic conditions affecting the culture medium, i. e., the stool in which it occurs, or in extrinsic causes affecting the surrounding atmosphere, or in conditions associated with both factors, such as heat, moisture and temperature. It may be premature or inexpedient to theorize as to the exact manner in which these various elements act, still we may presume that the difficulty lies rather in the culture medium than in the surrounding conditions, for while we can largely reproduce the extrinsic conditions, such as moisture, temperature, light, etc., we can not ever exactly reproduce the culture medium, for the latter in the tropics differs greatly from that of the temperate zones, both on account of the different foods which go to form it, and the different bacterial flora which it contains, the latter being much more varied and profuse in the tropics. In support of this view are Leichtenstern's recent observations (1899), that the sexually differentiated generation is cultivated most frequently from cases recently imported from the tropics.

I will later call attention to the disappearance of the parasite from the stools synchronously with that of the numerous bacteria which the latter contains. This condition, while not an invariable rule, is a coincidence of much significance.

The parasite may be arrested at an intermediate stage of its attempt at sexual differentiation, and accordingly, we may find the nematode in our cultures in three distinct states:

(*a*) No attempt at evolution may be made, and the parasite occurs only as the rhabditiform embryo.

(*b*) The parasite may be able to attain the male development, but be unable to attain the female type, a few male parasites occurring in the stool.

(*c*) Complete sexual differentiation may occur, and both male and female types will be found.

Whatever further development may now occur if the parasites are ingested, if still remaining external to the body the filariform embryo is finally produced; in the first case by direct transformation of the rhabditiform embryos, in the last case by the interposition of another generation of sexually differentiated worms.

Keeping these features in mind, how are we to regard the filariform embryo in its relation to the other types of parasites? If we regard the free sexual form as the highest type; as the filariform variety follows after this, it appears that the filariform embryo must be considered an involution form from the highest type. The filariform embryo is, moreover, the last form found in the specimen before the final disappearance of the parasite from the stool. This disappearance must occur, even under the most favorable conditions, in a rather short period. It is probable that the strongyloides embryo is more adapted to the relatively unfavorable conditions found outside the body, and is, moreover, the usual form in which the intestinal canal of the host is infected. If infection occurs in this way it is probable the filariform embryo becomes directly transformed into the parthenogenetic mother worm, which then commences to cast off its ova, and these, in turn, undergo development into the rhabditiform embryos. Leichtenstern has been able to demonstrate this process directly. He administered to human beings filariform larvæ which he had produced by the direct transformation of the rhabditiform variety. After seventeen days rhabditiform embryos were found in the patient's stools. In cultures these became transformed into the filariform

variety, but a number also became sexually differentiated, forming a free living generation, the *Rhabditis stercoralis*.

Leuckart claims that the genesis of the parthenogenetic mother worm is the essential step in the regeneration of the rhabditiform embryo from the filariform. He says, "The structure of the filariform embryo is such that they can not possibly develop again into the rhabditis form. There must be another worm which develops from them, which in the shape of its body and the structure of the esophagus resembles these." The parthenogenetic worm, the so-called *Anguillula intestinalis*, appears to represent this intermediate form which Leuckart considers essential. Hence, while the rhabditiform embryo is transformed directly into the filariform, the filariform can not return to the rhabditiform variety without the aid of the intermediate form. The development of this parthenogenetic worm has never been noted outside of the living host. These conditions probably explain the ultimate disappearance of the parasite from the stools, when the latter are kept for a certain period, the parasites continuing their evolution until the filariform embryo is produced, and beyond this they can not go without the aid of a suitable host. The rhabditiform, as such, does not seem able to survive more than three or four days in the stools.

To trace the life history of the parasite on the assumption of the unity of the various forms, we may conceive of a parasite entering the host as the filariform embryo; within the host becoming transformed into the parthenogenetic female, *Anguillula intestinalis*, the latter giving off numerous ova which, hatching rapidly before leaving the intestines, appear as the rhabditiform embryos (*Anguillula stercoralis*) in the discharges. The next transformation of the rhabditiform embryo depends on the environment. In the tropics the parasite becomes habitually sexually differentiated, forming the species known as the *Rhabditis stercoralis*, from the eggs of which are generated the rhabditiform embryos, which undergo final transformation into the filariform variety. In the temperate zones the rhabditiform embryo passes into the filariform without the interposition of the so-called *Rhabditis stercoralis*. In either event the filariform embryo is the final stage completing the cycle.

The first case in this country described of infection with the *Strongyloides intestinalis*, was that of a German tailor, aged 56, who entered the Johns Hopkins Hospital, Baltimore, Dec. 7, 1896. The case was complicated with intestinal infection with the *Trichomonas intestinalis* and amebic dysentery, which latter disease proved fatal on the development of an abscess of the liver. The parasite was discovered by Strong in the stools, and was reported, together with two like cases, by Thayer in 1901. Thayer's account of the case is summarized below:

CASE 1.—*History.*—K., a German tailor aged 52, was admitted to the Johns Hopkins Hospital Dec. 7, 1896, complaining of pain and swelling in the right side of the abdomen and over the lower ribs.

The family history was negative. He had had measles in childhood, but had otherwise been a healthy man. He denied venereal disease. Up to six years before he had lived in Austria.

Three years before entry he began to suffer from diarrhea, which has continued since that time. There were daily from two to five operations, which occasionally contained a little blood; these were never associated with pain. Three weeks before entry he began to notice a painful swelling on the right side over the lower ribs. He had had no chills, and as far as he knew no fever. For two weeks before entry there had been a slight cough without expectoration.

Physical Examination.—The patient appeared emaciated and feeble. The heart and lungs were negative. The abdomen was somewhat distended; there was slight movable dulness in the flanks. On the right side over the cartilages of the tenth and eleventh ribs there was a large fluctuating swelling, 7½ cm. in diameter; no tenderness or redness. Between this and the spinal column there was another swelling, about 15 cm. in diameter, extending from the median line to the spinous processes, and from the twelfth rib over the crest of the ilium downward for a distance of 7 cm. The skin over this was adherent, red and thin. The hepatic flatness was not increased.

Operation.—Immediately after entrance this abscess was incised and evacuated. The cavity contained a large amount of puriform material with dark shreds and considerable grayish debris. The cavities extended into the liver. About one and a half pints of fluid were evacuated; this contained many large, actively motile amebæ, showing the ordinary characteristics of the *Amœba coli*.

The patient had daily from two to four fluid, brownish, foul-smelling stools, which contained besides *Amœba coli*, considerable numbers of the *Trichomonas intestinalis*, as well as numerous small nematodes, identified by Mr. Strong as the rhabditiform embryos of the *Strongyloides intestinalis*. The wound and the colon were irrigated with a solution of quinin, 1/1000. The patient gradually failed, and died on December 26.

Autopsy.—The protocol of the autopsy reads: Amebic dysentry; ulceration of the large intestine; retroperitoneal abscess; operation wounds; parenchymatous and fatty degeneration of the kidneys; fatty liver; fatty heart; intestinal infection with *Trichomonas intestinalis* and *Strongyloides intestinalis*.

The large intestine showed the extensive ulcerations due to the amebic infection; the small intestine was free from ulceration, but showed slight occasional ecchymotic patches.

Along the whole of the small intestine Dr. Stiles and Mr. Strong found embryos of the *Strongyloides intestinalis;* and parthenogenetic mother worms were found in the duodenum and jejunum.

Dr. Strong was successful in this case in the cultivation of a single sexually differentiated parasite. This was of the male type, and was dead when discovered. No female forms were found.

The second case did not occur until nearly three years later. The symptoms of this case were chronic diarrhea and emaciation, and were not especially marked, and might easily have escaped the more superficial examinations, as it was only observed as a dispensary case. The case did not escape the vigilance of Dr. Thayer, in whose hands it fell, and the diagnosis was made almost as soon as observed.

CASE 2.—*History.*—A newsboy from Richmond, Va., where he had lived all his life. The family and previous history showed nothing bearing on the case. He had had the usual diseases of childhood, and five years ago had tertian ague.

Three years before entry the patient began to suffer from diarrhea, the attack coming on during the summer. The operations were very thin and yellowish in color, containing at times a small amount of blood, though this had not been noticed for a year and a half. The passages occurred mainly at night, as many as seven or eight in 24 hours, but of late only about four. There was at first considerable mucus in the stools, but this had been practically absent during the two years before entry. The diarrhea had never been associated with any pain. The patient had been, however, growing gradually weaker, and during the second year of his illness he had been compelled on one occasion to take to bed for two weeks. Four months before entry he gave up work on account of weakness, though up to that time he had felt tolerably well. The appetite was good. There were no dyspeptic symptoms.

Physical Examination.—A slight emaciated boy of sallow color. The lips and mucous membranes were somewhat pale; tongue clean. Examination of the heart and lungs was nega-

tive. The abdomen was not distended. The spleen was not palpable. No enlargement of the liver.

The patient entered the hospital July 7 and was put to bed and given a liquid diet. The only medication given at first was bismuth. Later the patient was, on two occasions, given thymol gm. 2 (gr. xxx), the dose being repeated after an interval of one hour, and following this an active purge. Male fern was given in like manner in doses of one dram.

The patient's symptoms improved greatly and he gained twenty pounds in weight. He was discharged at his own request August 26. The stools on discharge still contained moderate numbers of the rhabditiform embryos of the parasite.

CASE 3.—*History.*—A native of Maryland, who had never been out of the state except on an occasional visit to Washington. J. S., a farmer, was admitted to the Johns Hopkins Hospital July 19, 1900, complaining of diarrhea and swelling of the feet. The patient had been a farmer all his life; his habits have been good; he has had no serious illnesses except chills and fever fifteen years before entry. He had considered himself a healthy man up to six months ago, when he began to suffer from diarrhea and progressive weakness. The stools, very frequent and sometimes involuntary, were fluid, but never contained blood. They were small in quantity. During the two months before entry the patient had on several occasions vomited a yellowish fluid. For two days he had had sharp, griping pains in the lower abdomen. For a month there has been edema of the feet and legs. . . . During the last two months he has lost considerably in weight and much in strength.

Physical Examination.—Moderate atheroma of the radial, slight abdominal distension and flatness in the flanks. On examination a moderate number of characteristic rhabditiform embryos of the *Strongyloides intestinalis* were found, together with a few red blood corpuscles and large numbers of leucocytes. The temperature was slightly elevated, 100.6 F., on entry, but with the exception of an occasional rise to a point between 99 and 100 it remained subnormal during the greater part of the patient's sojourn in the hospital.

On entry the patient was given a milk diet and powders of tannogen and bismuth subnitrate, q. 4 hours . . . . on April 12 . . . he was given thymol, gr. v. q. 4 hours . . . . on August 13 the thymol was discontinued and four doses of santonin were given at hourly intervals. . . . the patient was considerably better. There was a gain of 21½ pounds in weight between July 29 and September 17, the date of his discharge.

The blood examination from all three of these cases showed moderate anemia, the hemoglobin in the first case of Thayer's series registered 48 per cent., and in Case 3 of this series 57 per cent.; in both of these cases, however, there were complications present; the first case was complicated by amebic dysentery, the last case with a probable renal sclerosis. The high leucocyte count observed in the first case is easily accounted for by the amebic infection. The presence of a hyperleucocytosis in Case 3 is hard to account for; the one count made showed 21,500 leucocytes to the cubic mm.; unfortunately, no further count was made. None of the three cases showed any eosinophilia. The differential count in the first case gave:

Polymorphonuclear leucocytes	88.3 per cent.
Small mononuclear leucocytes	7.5 per cent.
Large mononuclear leucocytes	2.4 per cent.
Transitional forms	1 per cent.
Eosinophiles	.3 per cent.

The blood count showed 3,412,000 r.b.c., leucocytes 32,100; hemoglobin 48 per cent. Twelve days later the eosinophiles had fallen to 0.1 per cent., and the leucocytes to 30,000. The *valeur globulaire* was little affected, the blood generally showing the changes similar to all secondary anemias resulting from loss of blood.

Thayer's second case is of much interest on account of the occurrence of a number of eggs in the stools. This is very rarely observed in infection with the *Strongyloides intestinalis* unless there also be present an uncinarial infection.

After the report of Thayer's cases no further cases were observed until the middle of 1902, when two cases were discovered within a few months of each other; one occurring in the practice of Dr. Moore at Galveston, Texas, the other case occurring at the University Hospital in Baltimore in my own service. This case I wish to describe in some detail:

CASE 4.—*History.*—Entered the University Hospital July 25, 1902, complaining mainly of a chronic diarrhea, which had lasted about five months. The movements varied from about 2 to 15 daily; average was about 10 to 12. Operations were painless and were not accompanied by tenesmus. Alvine discharges were watery and contained mucus. There were occasional slight griping pains in the abdominal region. Patient had lost about 15 pounds in the last three months. Occasional sweating was present, both at night and during the day and accompanying this mild rigors. There had been slight cough lasting about two years, and occasionally sharp pains have been felt in the chest. The patient was operated on about two years ago for fistula in ano. He lost two sisters from pulmonary tuberculosis, and his father died of the same disease at the age of 20.

Physical Examination.—Patient is a well developed man, rather thick set, of excellent physique with a clear, ruddy complexion, but with some slight pallor of the mucous membranes. Height 5 ft. 6 in. Weight about 135 lbs. His previous regular weight has been about 145 lbs.

Eyes.—Clear and bright, pupils react readily to light and accommodation. Palpebral mucous membrane a trifle pale. Lips showed some pallor and a faint cyanosis. Tongue was pink, moist and clean . . . . moderate enlargement of tonsils . . . no other glandular enlargement. . . .

Chest.—The thorax is large and well formed, costal angle about 45 degrees, expansion fair, equal on both sides. Both supra- and infraclavicular fossæ are well filled. Apices of the lungs rise about ¼ inch above the clavicles. There is good resonance over both clavicles and over the anterior thorax. Expiration a trifle prolonged . . . a few sonorous râles were heard . . . at the right apex posteriorly the respiratory murmur was roughened and the sonorous râles more numerous and an occasional clicking sound was heard. The voice sounds are considerably exaggerated. On percussion there is slight diminution of resonance and a slightly elevated pitch.

Heart.—Situation of the apex beat is normal, cardiac sound is clear, both at the apex and base.

Abdomen.—Hepatic flatness begins at the sixth rib and extends about ⅛ inch below the costal margin. The liver and spleen are not palpable. Abdomen is soft, no tenderness or tympanites. Lymphatics somewhat enlarged. . . . .

There were several possible conditions to be considered as the essential cause of this diarrhea. The tubercular history with the history of fistula, the occurrence of slight rigors and sweating with cough lasting two years, rather indicated a tuberculous process with ulceration of the bowel. The excellent physical condition of the patient, absence of emaciation and of glandular or peritoneal involvement were at once sufficient, however, to negative this assumption. It is seldom that extensive tubercular ulceration lasts more than a few months without some local or general peritoneal involvement. The long periods of remission are also antagonistic to this assumption. The absence of pain, the long remissions and liver enlargement, together with slight rigors, suggested an amebic infection. On examination of the first specimen of stool, however, a single parasite was observed. This parasite was very sluggish and its movements only lasted about half an hour, and owing to this fact, and to the examination being made at night, it was not possible to determine accurately its characteristics, but it appeared to be an uncinaria.

Examination of the Stools July 29.—Stool of semi-solid consistency, brown in color, odor not especially marked.

Microscopic Examination.—Red blood and pus cells abundant—fine granular detritis—few starch granules (in addition to the parasite already described).

Treatment.—The next day the case was seen in consultation with Drs. Thayer and Atkinson, and on passage of the rectal tube Dr. Thayer was able to find a number of the rhabditiform embryos of the *Strongyloides intestinalis*. The patient was put on liquid diet for twenty-four hours, and then on soft diet, and was confined to bed. The only medication given was small doses of quinin. Under rest and diet the symptoms abated greatly. The number of daily movements averaged about the same, but the involuntary evacuations of the bowels at night ceased.

Examination of the Stools August 2.—Granular detritis, pus and blood cells diminished; numerous motile and non-motile bacteria.

The stools were now examined daily. The occurrence of the parasites was very variable; occasionally the fecal drop would contain five or six specimens and at other times none would be found after a careful search through a number of specimens lasting two hours. The greatest number found in any drop of fecal matter did not exceed ten or fifteen. There appeared to be a constant relation between the number of parasites and the number of bacteria occurring in the stool. When there were no bacteria evident, on microscopic examination, the search for parasites proved futile; on the other hand, stools containing large numbers of bacteria usually contained numerous parasites. Nearly all the softer stools contained both bacteria and parasites. The stools, both microscopically and macroscopically, showed the presence of an intestinal indigestion. They contained during all of the diarrheal relapses undigested food, and the odor was usually offensive. In one instance fermentation had occurred, and bubbles of sulphuretted hydrogen were being given off rapidly. This specimen contained numbers of parasites.

A certain technic is necessary in the examination of the stools, and in the cultivation of the other forms of the nematode, especially if the endeavor is to be made to cultivate the sexually differentiated forms.

The stools as soon as passed should be placed in open vessels and kept at room temperature. It is best to divide the stool into three portions so as to observe the parasite under varying conditions. One specimen may be placed on the top of the sterilizer, one beneath and one at room temperature. A little normal saline solution may be added to the stools of the more consistent kind, the embryos having a tendency to collect in this portion. For examination, a considerable dilution of the drop is always necessary, otherwise the embryo, being almost transparent, will escape observation. It is best to commence the examination with the ¾-inch objective, and reduce the light somewhat.

Examination of the Blood August 10.—An examination of the blood was made August 10 with the following result:

Hemoglobin	82 per cent.
R. B. C.	4,672,000
Leucocytes	7,800
V. G.	0.88

A marked eosinophilia is present.

This moderate anemia gradually improved with the improvement in the general condition. The leucocyte count was practically normal, and never at any time showed a marked increase.

An eosinophilia was present sufficiently marked to be plainly evident on the examination of the fresh blood. Eosinophilia is not a symptom generally observed in intestinal infection with the *Strongyloides intestinalis*, and its presence in this case suggested strongly a condition of mixed infection frequently observed, viz., where the strongyloides and uncinaria are cohabiters of the intestinal canal. This condition strengthens the possibility that the first specimen observed was really an uncinaria. The eosinophilia in these cases frequently persists after the anemia and other symptoms have disappeared and the parasite has apparently been completely eradicated. A differential count was made some days later by Dr. Rankin, resident pathologist to the University Hospital, and he examined several stained blood smears at the same time:

QUANTITATIVE:		
R. B. C.		4,736,000
Leucocytes		7,860
DIFFERENTIAL COUNT, LEUCOCYTES:		
Polymorphonuclear	250	47.5 per cent.
Small mononuclear	157	29.6 per cent.
Large mononuclear	50	9.5 per cent.
Transitional	8	1.1 per cent.
Eosinophiles	61	11 per cent.
Cells counted	525	

Qualitative.—Red blood corpuscles show little change. No poikilocytosis and corpuscles uniform in size. Slight pallor. White blood corpuscles, polymorphonuclear leucocytes, show every variety of degeneration. (*a*) There is increase in eosin staining. (*b*) There is loss of neutrophilic granules. (*c*) There is vacuolization, fragmentation and loss of outline in the body of the cell. (*d*) Nucleus is enlarged, paler and shows clear vacuoles—hydropic degeneration. (*e*) Perinuclear basophilia marked. The nuclei also show supernumerary lobes in many cells. Small mononuclears vary considerably in size, are more granular and the nucleus often irregular. Large mononuclears much increased, show marked degenerative changes, principally in an increase in granules and considerable hydropic degeneration. The nuclei of many of these cells are much fragmented and many look as if they were undergoing karyokinesis. Eosinophiles vary considerably in size and in number of granules contained; but all the granules are uniform in size and of equal staining power. No iodophilia.

On August 21, commencing at 11 a. m., the patient was given thymol, grs. vii, every five minutes until twelve doses were given, the patient receiving in the hour gm. 12 (180 grains).

The patient had some abdominal pain and griping, not enough to give him any serious inconvenience, and experienced some slight nausea. He was freely purged, and eight specimens of the stools were obtained, containing an abundance of undigested food. Any further purgation was considered unnecessary. The patient was given no food for twenty-four hours previously. The specimens of stool contained numbers of embryos, all of which were dead. No specimens of the parthenogenetic worm were observed.

One week later the same treatment was repeated, thymol being again given in heavy doses and following this a purge. In the evening an enema of sol. of quinin was given (1 to 1000).

After this treatment the patient improved considerably and was able to resume house diet. Examination of the stools, however, showed actively motile rhabditiform embryos, though in diminished numbers. The patient was now much better, and during my absence from the hospital he was discharged.

He disappeared from view until the beginning of April of this year. He had gone over to Washington, where he sometimes lived, and experienced a severe relapse. He gave his history in one of the Washington hospitals, and learning that he had been treated for a "foreign worm" a specimen of the stool was sent to Dr. Stiles, who found numbers of embryos in it. Since then Dr. Stiles has made systematic examinations of the stools in about 150 cases, and has succeeded in adding to our knowledge of the occurrence of the parasite in this country, five additional cases.

(The conclusion of this article will appear next week with the two articles on the same general subject by Drs. Henry B. Ward and Claude A. Smith.)

To administer quinin to children, according to a French pharmacist, mix 1 gm. (15 gr.) of the sulphate in a mortar with 8 gm. (2 drams) of olive oil. Twenty drops of this mixture will contain 5 centigrams (¾ gr.) of quinin. The mixture is poured into a tablespoonful of sugared milk, and will be easily swallowed.—*Indian Med. Record.*

SHOULD THE TUBERCULOUS PATIENT KNOW THE TRUTH REGARDING HIS CONDITION?*

C. P. AMBLER, M.D.
ASHEVILLE, N. C.

All physicians who practice at health resorts frequented by patients suffering from pulmonary tuberculosis find that comparatively few of these patients have any conception of their real condition, and in the rarest instances have they been carefully instructed as to the necessities for recovery.

The profession generally seems to be of the opinion that tuberculous patients should not be told the nature of their trouble, but the average tuberculous patient generally finds out the true nature of his disease, and when he does he loses faith in his physicians, and frequently, very justly, will censure them for not telling him the truth.

How is it possible to get the coöperation of the patient; to have him use care in the disposal of expectoration; to avoid violence and over-exertion in exercise, and many other things so important in the detail management of the case, if he does not even know that he has a serious trouble with which to deal?

The truth may depress him; probably it will for a short time, but it will not do him near the harm that his ignorance will result in, if he does not appreciate his condition. Every state and municipality is awaking to the danger of infection from the dried sputum of tuberculous patients. Our journals are full of papers advocating antispitting ordinances, institutions for the tuberculous poor and other safeguards intended to protect the public. But why, pray, should we have ordinances and legislation unless the patient is always to know the truth? Legislation we need, but we first need more candor on the part of the physicians.

Formerly a diagnosis was only made in the advanced cases. The patients all promptly died. Result: the laity watched these cases and observed, "they all die." But little idea was ever entertained in those days of the danger to others. We, as physicians, by our tardy diagnosis, have educated the public to the belief that the disease is uniformly fatal.

It is the duty of the physician to explain to the patient the dangers to himself and to others; to point out where he is most apt to make mistakes; to give explicit directions regarding his hygienic life, including diet, exercise, work, physical or mental application, secretion and excretion, sexual relation, and in fact, to go fully into the whole question of the hygienic life. Such instruction on the part of the physician is much more important than the prescribing of drugs with an idea of "cure" in this disease. These instructions and directions should apply to the incipient as well as the advanced cases. To get the coöperation of an incipient case (and his coöperation is of the most vital importance) he must know the truth.

The patient should thoroughly understand the possibilities of communicating the disease to others, and also that he can infect sound tissues in his own lung if he is not careful in following directions for disposal of expectoration. How can we expect care on his part if he does not understand the danger, both to himself and his friends? Many will use care on account of their friends, and others more selfish can only be appealed to with good effect when they realize that they endanger themselves.

The laws of health demand that the patient fully realize the danger to self and others.

Appeal to the patient on the ground that it is unkind to his friends not to make every effort to protect them. If this plan had been followed more in the past the disease would not be so common to-day.

If tuberculosis produced the rapid disfigurement and distress that many of our acute diseases do, or was the active developing disease that smallpox is, we would have quarantined against it long ago. Its slow development makes it hard for the laity to realize that danger exists. Quarantine is unnecessary in tuberculosis, provided the patient is properly instructed and these instructions carried out. The whole country is awaking to the fact that something must be done. We, as physicians, should realize that one-sixth of our death rate each year is caused by tuberculosis; in other words, one-sixth of those who die this coming year in this country will die of this disease. Those who die from tuberculosis the two years following this, in the great majority, already have the disease in an incipient form. It is to their interest to know the truth to-day. It is to the interest of the general public that they know it; that they are fully instructed and cautioned. They consult us for this purpose; it becomes our duty to determine their condition early and so inform them. We have a duty to the other members of a family as well as the patient. Can the state house this great army of patients? Can we quarantine them if we would? No. How can we, as physicians, prohibit the infection of others? By educating the people to their danger and instructing the patient as to his duty.

Is there any way in which the necessary hygienic measures can be secured without the coöperation of the patient? Can we ever get his coöperation unless we tell him that he has a tuberculous disease?

The patient comes to us for the truth. It is our duty to show him that the disease is not the fatal disease that the public have imagined, if instructions be followed. Every physician should keep at hand printed matter, instructions or directions, to put into the hands of the tuberculous patients.

We have for years told our patients that this disease is like unto a fire in a house. If you get after the fire when the match is struck it is easy to put out; let it burn until one whole room is on fire and you have a much more difficult undertaking; let it burn until the house is on fire from garret to cellar and it is sure to burn up.

For the protection of our neighbors, as well as our own property, we all handle fire with care. If a friend's house is on fire would you tell him? A thousand times more important is it to tell him when we find that he is infected with tuberculosis; here the greatest possession he has on earth is at stake. The sooner he knows it the better.

By telling the patient the truth, we may occasionally shorten the days of a few, but in the long run will save the lives of many hundred by following this policy. Our surgeons operate to save life, even when grave danger exists by such an operation to the patient. If our tuberculous patients are not told the truth, the danger is not only to the patient, but to all his friends included.

It is an unpleasant duty to perform, but one from which no physician should shrink; and especially should patients never be sent away from home without knowing their true condition.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

How frequently are we consulted by some poor soul who had left home and arrived at the resort suffering, as he says, from a "slight throat trouble"; arrived may be in the beginning, and, perhaps, well advanced in pulmonary or laryngeal tuberculosis; without money, expecting to procure work to pay for his board and keep; arriving under the fond delusion that by climatic influence his trouble will soon disappear; with no conception of the necessities for recovery; no knowledge of the gravity of his disease; in many instances his chances were a thousandfold better at home among his friends, had he been told the truth, given explicit instructions, given less medicine and more time by his physician.

The tuberculosis patient who does not know his true condition rarely improves. As his case progresses he becomes discouraged and loses confidence in his medical advisers, thinking they do not understand his case. Can he be blamed?

On the other hand, the patient who is told the truth may temporarily be depressed, but he quickly responds and enters heart and soul into the fight before him. Rarely indeed do we find a patient who has been properly instructed and handled (without misrepresentation) who does not look forward to recovery. Phthisical patients are, as a rule, hopeful. Not so the patient who does not know what is the matter.

Intelligent pulmonary patients sent away from home without being told the truth frequently, from observation alone, find out their condition. When they make this discovery themselves it creates distrust of the physician at home and places the physician at the resort in an embarrassing position, where the truth from him now will reflect on the physician who may have referred the patient to him; or, he likewise must misrepresent the facts to the patient with the result that later he will be censured, with the home physician, for "not finding out what the trouble was."

True, there are exceptional cases where the patient is accompanied by the parent or some one who can control him, when the whole truth need not be given to the patient, but these cases are extremely rare. We have in the past relied too much upon drugs; we have been too free with our prescriptions and too careless in our instructions. If we would give the patients more of our time and less of our dope, it would be better for the patient. The good results obtained from institution treatment of this disease are dependent, in a great measure, on the fact that the patients know their condition and are under constant supervision and instruction.

For the good of our tuberculous patients; for the protection of their friends and the public generally; for the protection of ourselves, both physically and from censure, let us fully inform our tuberculous patients as to their disease, and when so informed take the time to properly instruct them what to do and what to avoid.

To secure the proper position of the profession requires its unification, and unification can only be brought about by efficient organization, which, in turn, must be preceded by the enrolling of those who are to be organized. It ought to be made very clear that the man who, being legally admitted to practice medicine, does not unite with the local society places himself in the same relation to the medical profession that a bushwhacker does to an army. That man who manifests no interest in his profession will, in the last analysis, be very apt to forget the proprieties to be exercised toward the individual physician with whom he may come in contact.—Editorial, *Lehigh Valley Medical Magazine*, June, 1895.

THE INFLUENCE OF CONSANGUINITY ON THE ORGANS OF SPECIAL SENSE.*

LEE WALLACE DEAN, M.S., M.D.
IOWA CITY.

In treating this subject I have found that I am compelled to confine myself almost entirely to the eye. It presents to us such possibilities for exact investigation that the results secured overshadow those gained from a study of the other organs of special sense.

We have here blood vessels and a nerve with its end organ exposed to view. We can look on mesoblastic and epiblastic tissue. We can observe embryonic conditions if they exist. With the exception of the nervous system, more degenerate conditions are found in the eye than in any other part of the body. As most of the deleterious results of consanguinity are degenerative conditions, we ought to expect this to be a good field for research. You will readily observe that this paper is not a complete treatise on this subject. It has been almost impossible to find literature relating to it. I can only give to you the results of three years of observation of cases and study of them.

It is entirely unnecessary to go into the question as to the influence of consanguinity on organism as a whole. Talbot very nicely answers this question when he says that if the parent stock is perfectly pure there can be no bad results from consanguineous marriage. But if the parent stock is not pure there may be serious consequences. It is so rare to-day to find a perfect parent stock. An apparently perfect stock may not be so because hereditary influences may be quiescent for generation after generation, as is shown by atavism. In order to bring before you the practical side of this subject and its economic importance, I wish to cite some cases. All cases where the name of the observer is not mentioned are cases that have come under my own observation unsolicited in the short space of three years. Some of these cases were reported to the American Academy of Opthalmology and Rhinolaryngology:

CASE 1.—Male, age 17. Parents, grandparents, uncles and aunts had no serious eye trouble or degenerate stigmata. Parents were bright, well-to-do people. He has three sisters, Bessie, age 15, who is partially blind; Effie, age 9, whose vision is good, and Grace, age 4, who is blind. He has three cousins, one boy and two girls, all in the same family. Of these, Louis, age 16, is almost blind; Oran, age 19, can not count fingers, and the girl, age 13, seems to have unimpaired vision. The trouble in each case was retinitis pigmentosa. The fathers of the two families were brothers and the mothers sisters, and the fathers were cousins of the mothers. As the result of these two marriages we have in one family four children, three of whom are partially blind, and in the other family three, two of whom are practically blind.

CASE 2.—Female, age 14. Father and mother have brown hair. Parents were related. There is no history of malformation or other degenerate stigmata in the family. The girl is very large, but weak; she is not intelligent. Her hair is white; iris is a light blue. Examination of eyes revealed nystagmus, V.=6/24. Fundi without pigment. Diagnosis, albinoism.

CASE 3.—Female, age 16. Parents second cousins. Patient's teeth were imperfect. She had but three upper incisors, one root germ not having developed. An examination of eyes revealed V.=fingers in 2 M. Her eyes are so small that she has to hold her lids open with her fingers in order to see. On the right side there is a congenital absence of the iris. In the left eye the cornea is elliptical, being 3 mm. wide in a

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

horizontal direction and 2 mm. in a vertical direction. On this side there is a large coloboma of the iris, one-half of the lower portion being absent.

CASE 4.—Male, age 17. Parents are perfectly healthy. None of his ancestors have shown any signs of degeneracy so far as could be learned. His father and mother were first cousins. He has one brother and two sisters. One of his sisters is an idiot. She has microphthalmos, misplaced ears and other signs of facial degeneracy. The patient is exceedingly simple-minded. His ears are large and placed at right angles to the head. The helix is deformed. His face is covered with a growth of silky hair. The lower jaw is exceedingly small and is retrusive. He has no adenoids, but always keeps his mouth open. Examination of the eyes reveals on the right side a microphthalmic eye with a coloboma of the iris and choroid. On the left side there was an apparent absence of the eye. There were two small lids and a socket. No eye could be felt by introducing the finger in between the lids and feeling about in the orbit. The lower part of the socket was deformed. The union between the malar and the superior maxillary bone had never taken place. There was a space one-fourth of an inch wide between the two bones. The patient was given an anesthetic and a dissection of the contents of the orbit was made. The fissure between the malar and the superior maxillary bone was found to extend back to the spheno-maxillary fissure. In the apex of the orbit, lying closely against the optic foramen, was found a rudimentary eye. It was removed. It was about one-third of an inch in diameter. With the naked eye no change indicating the cornea could be detected. The eye was hardened in formaldehyd and alcohol and stained with hematoxylin and eosin. The eye was composed of an outer thick fibrous coat. The cornea could only be differentiated microscopically from the sclera by the absence of an inner lining of pigmented cells. The eye was filled with a myxomatous tissue much more solid than the normal vitreous. It contained some blood vessels, one of which was very large. No trace of retinal elements could be found. The internal structures seemed to have all undergone a myxomatous and mucoid degeneration. The lens and retina seemed to be absent.

CASE 5.—This is not a single case, but the report of a family with six children. The father and the mother were both dark complexioned. There was no history of any degenerate condition in the family. They were first cousins. They had but six children. Of these, two were dark complexioned and had good vision. The other four were albinos and had a vision of 6/12 or less.

CASE 6.—Female, age 5. Parents were first cousins. No history of any serious eye trouble or of degenerate conditions in family. Child was very dull. Left eye began to enlarge shortly after birth. O. D. apparently normal. O. S. very much enlarged. Tension normal. Diagnosis, congenital glaucoma left. The left eye was enucleated. The usual cupping of the disc was present. Microscopic examination failed to reveal any obstruction of the canal of Schlemm.

CASE 7.—Female, age 6 months.. This case I saw in consultation with Dr. Cooling of Wilton Junction, Iowa. Parents were healthy. No history of any tumor or eye trouble in the family could be elicited. Parents were first cousins. The parents said that two months before the right eye began to increase in size and a few weeks later the left began. The child apparently could not see. Pupils were dilated; would not react to light. Tension in right eye +2, and in the left +1. Both eyes were enlarged, the right the more. Lying behind the iris in each eye could be seen a large tumor. Diagnosis, double-sided neuroepithelioma. Four months after the child was seen it died.

CASE 8.—Male, age 4. Parents' and grandparents' history negative. Parents cousins. Boy has congenital coloboma of iris in each eye and anterior polar cataract in the right eye.

CASE 9.—This is a family reported by Dr. Vail. Parents cousins. Consanguinity was positively denied for a year. Parents' and grandparents' history negative. As the result of the union seven children were born. Five had congenital cataract. The cases were so helpless that Dr. Vail recommended that no more children be born.

CASE 10.—Dr. Alt reports a family in which there is constant intermarriage. Senile cataract is hereditary in the family. In the last generation several cases of congenital cataract have made their appearance. If there is any relation between the senile cataracts and the congenital the former must be hereditary cataracts not the result of a sclerosis of the nucleus of the lens, but rather a nutritive disturbance. One could not think of the former condition appearing in children.

CASE 11.—Female, age 12. Parents' history negative except that they were first cousins. Is an only child. Has simple atrophy of the optic nerve.

Of 181 blind children in the Iowa College for the Blind in 1900, 9, or about 5 per cent., were the result of consanguineous marriage of the first degree. The number of consanguineous marriages of the first degree in Iowa is far below 0.5 per cent. I ought to say that it is exceedingly difficult to secure a history of consanguineous marriage when present. There were probably others present in the college the result of consanguineous union.

If we exclude from the list those blind children who were blind because of blennorrhea neonatorum, sympathetic ophthalmia, trachoma, etc., and consider only those who suffered because of congenital conditions, we would find that 14 per cent. were the result of consanguineous marriage of the first degree. These figures seem large. I do not think they ought to be considered as indicating the relative proportion of degenerate eyes in families the result of consanguineous marriage and in those not, because we are considering here only one field. Among the pupils who have entered the college since 1900 the per cent. is about the same.

Two factors may enter into the production of many of these conditions: 1. The eye is really an outgrowth from the brain, and is consequently subjected to the same conditions as the central nervous system during its development. 2. The eye is changing, and an organ that is adapting itself to new conditions is more liable to malformation than one with a constant condition. The socket is becoming less deep and the superciliary ridges less marked. Fuchs believes that in families with school myopia the eyes have adapted themselves to their work.

A number of interesting things are suggested by these cases: 1. The relation of the inheritability of a condition to its production by consanguineous marriages. I would judge from these cases that the greater the inheritability of a condition the more liable is it to be the result of consanguineous marriages. Theoretically, this would also be the case. Retinitis pigmentosa is a disease of great inheritability. I have now under observation a grandfather, a mother and a son each with retinitis pigmentosa. As it is a comparatively rare condition there is not the chance for doubting the tendency of its appearing by marriage of individuals not related as the more common conditions.

The influence of consanguinity on retinitis pigmentosa has been mentioned by several. Dr Liebreich says that of 26 cases of retinitis pigmentosa, 53.8 per cent. were the result of consanguineous marriage. Magnus reports 33 per cent. of cases of retinitis pigmentosa in children, the result of consanguinity. Of 66 cases reported by Chapault, 45 per cent. were the result of consanguineous marriage. Of 18 cases under my observation where the history of the parents could be secured, 8, or 44 per cent., were the result of

consanguinity. Schobel[1] says it is generally dependent on consanguinity. A very careful examination into the history of the ancestors of the cases I mentioned failed to reveal any eye trouble of importance. Yet in the first group mentioned we have these cases appearing by intermarriage in the two groups when consanguinity took place. Albinoism has a strong inheritability. Congenital cataracts have also strong inheritability. Most of the cases mentioned were not true cataracts, but capsular opacities, the result of non-absorption of fetal structures. In approximately one-third of the cases, however, the capsule was not opaque, but the lamellæ were affected.

Some light may be shown on the cases reported by Dr. Alt, where congenital cataracts appeared in the offspring of relations suffering from senile cataract by the fact that hereditary cataracts some time appear earlier in each succeeding generation. I know of a case where the grandfather developed cataracts at about 50; the mother had one at 35, and the son had congenital cataracts.

2. It is interesting to note that where there is an arrest in development, as in the cases of microphthalmos, coloboma of the iris, congenital cataract, and anophthalmos, the eyes are in an opposite state to those of eyeless fishes and worms where they have been lost by disuse. Wagenmann[2] has found that the lens and the retina were almost the least of the structures acted on, and that the phyletic degeneration does not follow the reverse order of development. The eye does not resemble part embryonic conditions as in the eyes where there is an arrest of development. At birth the eye is almost normal, but with age it degenerates. The microphthalmic eye improves the first ten years after birth, owing to a diminution of the hyperopia. A third point in connection with these cases is the resistance after operative procedures. Dr. Gruber of London writes me that he has operated on a number of such eyes with good results. I have never seen any serious sequelæ following an operation. While there is an arrest of development, the nutrition is apparently normal.

As to the influence of consanguinity on the neuro-epithelioma, I would certainly not express any opinion. I simply mention the case as I found it while conducting my investigations.

DISCUSSION.

DR. J. W. FOSS, Phoenix, Ariz.—This subject of inbreeding is given a great deal of attention by stockmen, but is neglected by human beings. About two months ago I visited an ostrich farm near Phoenix, and they had just hatched out eight or ten chicks, and out of the lot, because of physical deformities, there was only one it was possible to save. This was the result of interbreeding. It costs so much to get a male ostrich from Africa that to save expense they interbreed and get few perfect offspring as a result. This paper gives us the key to our duty as physicians, and we can prevent many of these consanguineous marriages by firmly and persistently impressing on our patients and friends the unfortunate results of such union.

Sylvius the Medical Grammarian.—J. D. Sylvius, M.D., born in 1478, whose name is so associated with the anatomy of the brain, was a famous grammarian in his day and wrote a popular Latin grammar. The *Gaz. Méd. de Paris* states that he was the first to propose and use two distinct letters for i and j, and for u and v. He was also the originator of the French accents, distinguishing between the three sounds of e: e, è and é. Several members of the Estienne family, the celebrated printing firm, were physicians, likewise.

New Instrument.

A PERITONEUM KNIFE.

JOHN R. COOK, M.D.
FAIRMONT, W. VA.

The accompanying illustrations show a new instrument, a peritoneal knife, which I have found a very convenient device for quickly enlarging the peritoneal opening after making the

opening in the usual way. The beak of the knife slides just under the peritoneum, hugging the same closely, and in this way all danger of wounding the intestines is eliminated.

I also find it very convenient in enlarging the abdominal ring in operations for the reduction of hernia. As will be seen, the blade is long and will divide all tissues, if necessary, from within outward.

THE FUNCTION OF THE CORPUS LUTEUM.

Everything about the structure of the corpus luteum suggests that it is of glandular nature. If one is examined at about the time of the implantation of the ovum it is seen to consist of rows of succulent cells radiating out from the center, resembling closely the structure of a liver lobule, not the cortex of the adrenal; that is, it resembles a true secreting gland. If it has an internal secretion such as the other organs it would naturally seem that this secretion must play some part in either menstruation or pregnancy, or more likely both, for it appears and disappears with menstruation, and reaches its highest development during the first months of pregnancy. This last indicates most probably a relation to the first phenomena of pregnancy, such as the implantation and the development of the ovum. This phenomenon of the preparation of the uterus for the reception, implantation and development of the ovum has always been mysterious, but it has also been evident that it could not be brought about by the fertilized ovum itself, for the changes are most rapid at the time when the ovum has neither vascular or nervous connection with the uterus and when it is still far too small to be of effect as a foreign body. On the other hand, these preparatory changes in the uterus occur when the corpus luteum is proliferating most rapidly, and in the later months of pregnancy when the corpus luteum is beginning to retrogress uterine growth is much less, and seemingly secondary to the rapid enlargement of the ovum. Furthermore, all animals that have a uterine insertion of the egg have a well-developed corpus luteum; those that discharge the undeveloped egg have either a rudimentary corpus luteum or none at all. These suggestive facts seem to have first been put together by the late Gustav Born, who developed from them the hypothesis that the corpus luteum of pregnancy must be a gland with internal secretion, the function of which was connected with the implantation and development of the fertilized ovum.

During his last sickness he requested L. Fraenkel to undertake the work necessary to the proof of this hypothesis and Fraenkel's[1] recent publication of his study is most interesting, and seems to constitute a distinct addition to our knowledge of the puzzling phenomena of menstruation and ovum implantation. Not only was Born's idea found to be correct, but it was found to be but part of a general law, namely: The corpus luteum during the years of generative activity produces through its internal secretion increased size and turgor of the uterus, as well as the periodic monthly hyperemia. This secretion accomplishes favorable conditions for insertion and growth of the ovum, or, impregnation failing to occur, it produces menstruation. If corpora lutea are lacking atrophy of the uterus occurs, and menstruation is absent. The condition of the uterus before puberty as well as after the climacteric depends on the absence of corpora lutea. In determining these facts rabbits were used, since in them the time of occurrence of the various series of events in the early stages of pregnancy have been pretty well worked out. It has been long known that removal of the ovary during the early part of pregnancy prevented maturation of the ovum, but Fraenkel found that a similar result was constantly obtained by simply burning out the corpora lutea, leaving the rest of the ovary intact; if a small part of the yellow bodies was left pregnancy was not always checked. In rabbits this influence seems to last through about twenty days of pregnancy, which is comparatively longer than is the case in women, since operative removal of ovaries as early as the third month has not always checked pregnancy. The effects produced by the corpus luteum seems to be chiefly through its influence on nutrition. As much atrophy of the uterus was found to follow simple destruction of the corpora lutea as after complete removal of the ovaries. A number of cases were found in the literature that seemed to Fraenkel to indicate that abortion in women with ovarian tumors has resulted from involvement or injury of the corpus luteum. There are also several instances of hydatid mole occurring in women with bilateral ovarian tumors, probably too many to be dismissed as merely coincident.

The relation of these bodies to menstruation was shown by burning the corpus luteum of menstruation found in the ovaries of women having regular periods, who were being operated on for malpositions or similar troubles that did not interfere with the observations. This addition to the operation is harmless, since such corpora naturally undergo resolution. The result in eight out of nine cases was that the next menstruation that was due was skipped, the succeeding menstruation occurring regularly as before. This seems to warrant the inference that the corpus luteum of one menstruation causes the next menstruation, in some way as yet not known.

When summed up it will be found that these studies simply enabled us to localize certain influences that the ovary has long been known to possess in the corpora lutea. The next step in order is the isolation of the active substance that the lutein cells secrete into the blood, as has been done with the thyroid and adrenal, and then we shall wish to learn how it acts, whether by vasomotor changes, or by directly affecting metabolism in the uterine tissue.

1. Archiv f. Gynaekol., 1903, lxviii, 438.

A certain practical result has already been found. Fraenkel was able in nearly all cases of operatively produced premature climacteric to greatly modify the symptoms by administration of lutein tissue from the cow, while at the same time further establishing his experimental results. Such lutein tissue is not difficult to obtain, since a large part of the bovine ovary consists of corpus luteum, and the results that he publishes warrant further trial of the substance as indicated by various conditions, particularly since it has been found to be harmless in any case.

MODERN LONGEVITY.

At the late actuarial congress in New York City, the subject of improved longevity was discussed and certain views expressed that have caused some sensational newspaper comments. It was declared by one speaker, according to the press reports, that the increase of average longevity was associated with a general degradation of the race. The increase of vitality was not in the strong, the results of sanitary reforms and of medical advances in the management of disease were only a diminution of mortality of the weakly and consequently a reduction of the general average of vigor and physical well-being in the mass. In other words, it is an interference with the process of natural selection by which the races of animals, man included, advance from the lower to the higher grades of physical perfection and being. This is not a newly discovered truth; it has long since been pointed out that mankind, especially in its social and recent development, does not come under the usual rules of natural selection—but naturally such an utterance captures the attention and is magnified by the press reporter.

There is more than one aspect in which this matter can be viewed. Undoubtedly we perpetuate the existence of many who are not the best samples of our race in the increased average longevity and the racial physique may apparently suffer. The survival of the helpless, the insane and all the defectives who would succumb under less artificial conditions also add to our "burdens," but it seems to us an error to say that the general result is race degeneration. The evolution of the human species has been intellectual rather than physical and at his present stage of development man is, as an animal, a degenerate. Physically, he is a weakling compared to his fellow animal in the jungle and pasture, but his better organized brain makes him incomparably their superior and their master. On an economic basis alone, the Spartan system of destroying the weaklings in infancy or the less ancient method of accomplishing the same result by neglect and ignorance is a fallacy. Every infant that dies at birth or in its period of helplessness is an instance of wasted human labor, and every one that is carried over to its age of helpfulness and productiveness is a possibility for the advancement of the race. Why this possibility is not always realized is a sociologic, not a medical or actuarial problem.

It is quite possible if not, indeed, probable, as has been pointed out by a recent writer,[1] that, while the average longevity is increased under better sanitation and with the advances in medicine in civilized communities, the number of instances of extreme longevity is diminished, and that we will find most instances of extreme old age in the lower, but not the lowest grades of civilization. Absence of stress and worry are the chief favoring factors of extreme longevity, and these are not so commonly associated with the complex conditions of modern civilization as with former patriarchal or feudal conditions. There is, moreover, a very material reason for the apparent diminished number of centenarians in highly civilized countries, the evidence is better sifted, and, as we have before pointed out,[2] the errors of ignorant persons as to their own excessive age are more frequently excluded. Those countries that have the most reliable vital statistics report the fewest cases that have passed the century mark. The fact that we do have so many instances of extreme age under modern conditions, together with an increase of average longevity, is good evidence of what the advance of medical science has done for the race. The further fact that the weaklings are preserved does not overbalance the general gain, and the prophecy of race degeneration from this cause may be safely disregarded.

THE SIMILARITY OF SERUM COMPLEMENT AND THE DIGESTIVE ENZYMES.

While the action of complement has long been likened to that of a ferment, that it is such, or is the same as the ordinary enzymes with which we are familiar, has never been established. It is strikingly like the proteid dissolving enzymes, especially trypsin, in the following particulars: It dissolves proteid substances, such as the bodies of red cells, of bacteria, or for that matter any other sort of cells to which it may be attached by a suitable amboceptor; it is not entirely specific for different substances; it acts best in a medium with a certain degree of alkalinity; it is destroyed by a degree of heat quite comparable to that destroying enzymes. On the other hand, it has not yet been demonstrated that cell solution by serum leads to the production of the various digestion products of proteolysis by which trypsin or other proteases are characterized. The known relation of complement to the leucocytes has suggested that it might be the same as the protease with which the leucocytes accomplish their remarkable feats of solution of digestible foreign and dead substances. The fundamental importance of complement in resistance to bacteria through bacteriolysis makes any light on its nature of particular value, and, therefore, the demonstration by Delezenne[3] of the similarity of action of the pancreatic and intestinal juices with that of the amboceptor and complement in producing cytolysis is of interest.

1. J. M. French, Med. Exam. and Prac., August, 1903.
2. THE JOURNAL, xl, p. 995.
3. Comptes Rendu Soc. Biol., 1903, No. v. 171.

We have recently spoken of the discoveries in the field of pancreatic digestion, showing that the enterokinase of the intestinal juice is essential to tryptic action, because it makes active the otherwise inactive trypsinogen which the pancreas secretes into the intestine. This action of enterokinase on trypsinogen Delezenne shows to be quite similar to that of amboceptor on complement, and he does it in the way that has yielded most of our information concerning complement, through a study of hemolysis by pancreatic juice. If red corpuscles that have been thoroughly washed with salt solution are placed in inactive pancreatic juice, that is, fresh pancreatic juice obtained pure through a fistula without coming in contact with the intestinal secretion, they are not at all affected for several hours. Pure intestinal juice, with its contained enterokinase, agglutinates them, but causes no hemolysis whatever. On the other hand, mixtures of the two, in which there is an active trypsin, dissolve the corpuscles very quickly. That this action is similar to that of amboceptor and complement the following experiments show: Red corpuscles are placed in each of the two tubes, one containing only intestinal juice, the other only inactive pancreatic juice, and they are allowed to stand in the cold for two hours. Then the corpuscles are repeatedly washed in salt solution, which frees them from any enterokinase or trypsinogen with which they are not united by other than physical means. If, now, the corpuscles that have been treated with enterokinase have inactive pancreatic juice added to them they are promptly dissolved, showing that the enterokinase had been combined with the corpuscles in a manner preventing it from being washed away, and from this site had made the trypsinogen active. On the other hand, when enterokinase was added to the corpuscles that had been treated with trypsinogen no dissolution of the corpuscles occurred, showing that the trypsinogen had been washed out completely, not having been united as had the enterokinase. In other words, enterokinase acts like amboceptor, uniting the corpuscles to the trypsinogen, which behaves like complement.

Whether the usual method of action of pancreatic juice in dissolving proteids is similar to this or not could not be finally determined, for albuminous bodies, particularly fibrin, have a way of entangling enzymes which makes it impossible to wash all the enzyme out, so that the above described experiments on red corpuscles could not well be repeated on foodstuffs. However, as far as experiments could be performed they indicated that this is the mechanism of pancreatic digestion. Ehrlich's conception of intracellular food receptors is thus shown to be very possible, indeed. As to the question of the proteolytic nature of complement as it exists in the blood, Delezenne's experiments seem to give rather a negative answer, at least so far as any identity with trypsin is concerned. In hemolysis by enterokinase and pancreatic juice the hemoglobin is not only liberated from the stroma of the red cells, but also decomposed and hematin is formed, whereas in hemolysis by serum the action seems to be limited to the liberation of the hemoglobin.

MEDICAL DEFICIENCY IN THE SOUTH AFRICAN WAR.

The report of the Royal Commission on the South African war takes up at some length the question of the medical management. While this subject has been treated by the special commission in 1900, they nevertheless again discuss it and find occasion for criticism of some defects similar to those which were developed in our brief Spanish war, such as insufficient personnel, defective sanitary organization, imperfect transportation facilities, etc., and some that we did not hear of, such as antiquated and cumbersome supplies, medicines twenty years old and instruments that should only be found in museums at the present time. We had more excuse for our deficiencies; we had a little army of 25,000, fairly well equipped, but this equipment and personnel could not be extended impromptu over a volunteer army of 250,000. In England they have a standing force of between 200,000 and 300,000 men, much of it in active service in some parts of the world all the time, and there would seem to be less reason why the defects above mentioned should exist in their case than in ours. The point is made that in a country with such facilities for supplying everything at need, it is useless to try to keep up large stores until they become antiquated and comparatively non-effective. Further, with colonial extension requiring more or less constant active service, it is reasonable to ask why the government should not be more ready for such emergencies as the Boer war. It is true the demands were extreme, and considerable excuse can be given, but the fact that the equipment of the colonial contingents and of the Boers themselves was generally so much better in many respects makes it appear that there had been too much red tape and official neglect somewhere. We do not mention the report as anything satisfactory to us because misery loves company, but simply because it is our business to learn as many valuable lessons as possible from other's experience as well as from our own.

THE LUST OF SLANDER.

Under the above heading, the *British Medical Journal* comments, July 25, on an appeal made the week previous by a deputation from the British Union for the Abolition of Vivisection before the Home Secretary of Great Britain. The deputation not only asked for a more rigid enforcement of the laws regulating vivisection, but for the enactment of more stringent ones. The deputation made use of the old arguments, and, of course, brought in the threadbare one to the effect that Sir Frederick Treves had stated that his experiments on animals had not been of service, for when he went to South Africa and operated on the soldiers the results obtained were quite different. As it happened, the Home Secretary knew something about the matter, for he stated that Sir Frederick Treves had repudiated the statement. He also informed them that the laws were being enforced and that he, for one, would not advise more rigid laws. Among those who appeared for the antivivisectionists

was a reverend gentleman who stated that watching these operations, i. e., vivisection, "induced a callousness that in time, in some cases, developed into a feeling of positive pleasure," and so on. The *British Medical Journal* analyzes the arguments presented and shows the basis for much of the "rot" that is being used as arguments by these zoöphiles. Among other arguments referred to is one credited to a "Dr. Leffingwell, an American antivivisectionist," a name that sounds very familiar in connection with antivivisection literature of this country. It occurs in an article which appeared in the *Abolitionist*, the official organ of the British Union for the Abolition of Vivisection, for 1901, entitled "A Terrible Revelation: Vivisection and Sexual Psychopathy," the terrible revelation being that "vivisectors make use of the sight of dying animals or torture animals to stimulate their lust." This statement, it is reported, is made on the authority of the above-mentioned American and by some unnamed person whom he cites as saying: *"En France on prolonge les vivisections pour se procurer d'infames plaisirs."* *American Medicine*, in commenting on this Leffingwell accusation, August 22, says:

It suggests a depth of degradation to which not even an antivivisectionist, and least of all an American, could fall. And now in the name of decency we call up Leffingwell—until he cleans himself not even Mr., surely not Dr.—to do one of two things: categorically and absolutely to deny that he ever made such a charge, or prove, up to the hilt, that it is true. Silence, or any characteristic antivivisectionist prevarication and indefiniteness, will leave him branded as poltroon and liar.

Thus far we have seen nothing from the Leffingwell referred to and we are waiting patiently. It is barely possible that he does not read medical journals, or possibly only such parts as may be twisted around to suit him in some of his "arguments." The old saying that "silence gives consent" we shall take to be true in this case, and certainly Leffingwell will be proud of the honor attached to him in having made such a dastardly accusation.

Medical News.

DISTRICT OF COLUMBIA.

Twelve Passed Examination.—Out of 22 physicians recently examined for appointment as medical inspectors of public schools, six passed; and of 11 examined for appointment as physicians to the poor six also passed.

Washington Suicides.—During the fiscal year just ended 54 deaths occurred by suicide, 22, or nearly 70 per cent., more than for the previous year. The revolver was used in 15 cases, carbolic acid in 11, and strangulation in 9.

Nonagenarian Illicit Practitioner.—Brooks Johnson, a colored individual claiming to be 98 years old, was recently arrested on the charge of practicing medicine without a license. The complaints allege that he offered to remove "spells" for $25.

Application Denied.—Dr. William C. Woodward, secretary of the Board of Medical Supervisors of the District of Columbia, has informed the commissioners that the board refuses to grant Salina Armstrong Hopkins, M.D., a license to practice medicine in the District, as the papers filed by her are not sufficient to warrant the issuance of a license without fee or examination.

Weaning of Children Fatal.—Dr. William C. Woodward, health officer, in commenting on the alarming death rate among infants from diarrheal diseases, says:

Weaning of children during the heated season is seldom recommended as a matter of choice, but only as a matter of necessity. In most instances the deceased infants were said to have been well developed and healthy and to have thriven so long as they were fed on mother's milk. The fatal change began with the substitution of other foods. The cause most commonly alleged for such substitution was the necessity under which the mother found herself of earning her own livelihood. Condensed milk seems to have been selected in most cases because of its convenience and not because of any intelligent belief in its superior merit. No effort was made to skimp on the price of this article. In only one case was a cheap brand used, and that was by no means the cheapest.

Those having the care of the babies seem generally to have been ignorant of the necessity for a proper water supply for such children. Little water was given as a rule, and even that small amount was Potomac water, unboiled. Nipples on bottles were but fairly well cared for. The sanitary condition of many of the premises in which these children lived was bad.

ILLINOIS.

Library Donated.—Charles C. Truesdale has donated the medical library of his father, the late Dr. Calvin Truesdale, to the Rock Island public library.

Anthrax Reappears.—Anthrax has broken out in the herd of cattle at Staple Farm, north of Palatine. Two years ago an outbreak of the same disease occurred in this section.

Personal.—Dr. Buenaventura H. Portuondo, Belleville, has been appointed commissioner of Cuba to the World's Fair, and also consul of Cuba at St. Louis.——Dr. Oscar Yarnell, Cerro Gordo, has gone to Europe.

Chicago.

The American Association of Obstetricians and Gynecologists meets in Chicago, September 22 to 24. The local members of the association are making arrangements to entertain those who attend with lunches, banquets, etc. The meetings will be held in the law library of the Northwestern University Building, corner of Dearborn and Lake streets.

Pasteur Institute Incorporated.—The Chicago Pasteur Institute has been incorporated by A. P. Lagorio, Carlotta Lagorio and B. G. Bruno, with a capital stock of $2,000, to treat hydrophobia.

Arrests.—Dr. L. Slominski and F. Eisen-Bockius have been arrested, charged with criminal malpractice.——Dr. Alfred Dahlberg has been arrested, charged with selling "cocain and other narcotics without a physician's prescription."

New Location for Temperance Hospital.—The directors of the Frances E. Willard National Temperance Hospital have decided to erect a $75,000 building on Lincoln street, between Polk and Harrison streets. The lot has been paid for, and there is $25,000 for a building fund on hand.

MARYLAND.

Baltimore.

August Deaths.—During August there were 860 deaths, 39.77 per cent. being of persons under 5. Of the causes of death the following were most prominent: Diarrhea and enteritis, 136; tuberculosis, 101; heart disease, 55; Bright's disease, 48; cancer, 37; pneumonia, 30; typhoid fever, 26; apoplexy, 24; scarlet fever, 11; whooping cough, 10; dysentery, 9, and diphtheria, 7.

Johns Hopkins Faculty Changes.—The following changes have been announced in the Johns Hopkins Medical School: Dr. Norman McLeod Harris has accepted a position in the bacteriologic department in the University of Chicago. Dr. Glanville G. Rusk, assistant in psychiatry, has accepted a position with the Pathologic Institute of New York. Dr. Burton D. Myers, assistant in anatomy, has an appointment as instructor in anatomy in the Indiana State University.

Personal.—Dr. Thomas Cullen has gone to his camp in Canada to spend a month. He has as his guest Dr. Howard A. Kelly, who returned from Europe August 29.——Dr. L. Ernest Neale has returned from Europe.——Dr. John Ruhräh has returned from a trip to England, Ireland and Scotland.——Dr. Joseph E. Teard is at Governor's Run on Chesapeake Bay.——Dr. William B. McDonald is at Capon Springs, Va.——Dr. Albert Shelley has gone to England.——Dr. J. Staige Davis is at Eaglesmere, Pa.

Johns Hopkins Ex-Internes.—Movements of former members of the staff are announced as follows: Dr. J. Auer has gone to Chicago to practice; Dr. J. B. Briggs has been made a member of the permanent staff of the hospital; Dr. Camillus Bush has been appointed assistant resident surgeon; Dr. J. W. Churchman is to be associated in practice with Dr. Hugh Young, Baltimore; Dr. H. W. Cook has been appointed resident physician at the Memorial Hospital, Richmond, Va.; Dr. M. L.

Haviland will practice in New Jersey; Dr. C H. Horst is to remain temporarily at the hospital. Dr. E. W. Meisenhelder has received an appointment in the Varnes Hospital, Washington, D. C.; Dr. C. B. Wright will remain temporarily at the hospital; Dr. F. W. Lynch, resident obstetrician, is going to the University of Chicago, and Dr. H. T. Marshall, assistant resident pathologist, is going to Montana on a mission for the United States Bureau of Animal Industry.

MASSACHUSETTS.

Personal.—Dr. George L. Richards, Fall River, is recovering from typhoid fever.

Smallpox Difficulties.—The board of health of Fall River is having much difficulty in stamping out smallpox. Recently a house was forced open by the police with axes and two men ill with the disease were found hidden, and removed to the hospital.

Mortality of Boston.—The mortality in Boston still continues low for this season of the year. The total number of deaths for the four weeks ended September 5 was 798, 42 less than during the same period last year and an annual rate of 17.23 per 1,000. Deaths under one year numbered 248; under 5 years, 302. There were reported 17 deaths from diphtheria, 2 from scarlet fever, 15 from typhoid fever, 78 from tuberculosis, 3 from pertussis, 63 from heart disease and 25 from marasmus.

Tuberculosis Aid and Education Association.—A new association whose objects are "to cure at home if possible persons suffering with tuberculosis; to relieve with food, so far as possible, all needy tuberculous persons; to educate the entire community in the care and prevention of this disease; to promote the establishment of hospitals for hopeless cases," hopes soon to commence active work in Cambridge. Mrs. Rufus P. Williams is chairman of the committee; Dr. John L. Hildreth, Cambridge, is chairman of the advisory board, and Dr. Edward O. Otis, Boston, advisory expert.

The New Harvard Medical School.—The plans for the first group of buildings of the New Harvard Medical School recently filed call for five buildings, fireproof, with white marble walls. The administration building, 166 by 124 feet, and 5 stories high, will cost $535,000; the physiologic laboratories, 196 by 148½ feet, 3 stories, $421,000; the laboratories for bacteriology and pathology, 185 by 128 feet, 3 stories, $390,000; histology and anatomy get a three-story building, 196 by 148 feet, and costing $396,000, while pharmacology and hygiene will be studied in a three-story building 185 by 108 feet, to cost $346,000. All are to be erected beyond the fens on Longwood avenue, on the lot which extends through to Francis street and Huntington avenue.

Out-Patient Department Opens.—September 1 the new outpatient building of the Massachusetts General Hospital was opened. It is a large three-story building, on the western side of the hospital grounds, with entrance on N. Grove street. It forms part of the new group of buildings already planned, and partly built, which will entirely inclose the open grass plot, on one side of which stands the old hospital designed by Bullfinch. This new building is complete in all its equipment, special efforts being made for asepsis, extension apparatus for specialists and the best means for clinical instruction. A unique feature is the card catalogue system of keeping case records, which are all kept at the central office and sent to the treatment room by dumb-waiter and messengers. Daily notes are made by the physician and the record thus returned to the central office and filed. An abundance of cross references will make this centralized record bureau of great value to anyone looking up special diseases.

MICHIGAN.

Smallpox.—The State Board of Health reports smallpox present at 37 places in the state.

Donation to Hospital.—From the receipts of the firemen's tournament recently held at Calumet $1,000 has been given to the building fund of the new St. Joseph's Hospital.

Michigan Standard Too Low.—The president of the Canadian Medical Association, in an address, declared that although Michigan was constantly raising her medical standard it was still too low even to be considered by the Ontario Medical Council.

Sent to Jail.—Dr. Richard L. Cornwell, Montague, has been sentenced to thirty days' imprisonment on a charge of non-support.——Paul Newton, claiming to be a "professor in Belleview Hospital, Chicago," was arrested at Benton Harbor, September 2, charged with obtaining $200 by fraud from a farmer at Sodus on an alleged contract to cure the farmer's wife of asthma. Being unable to furnish bail, he was sent to jail.

Personal.—Dr. Edward P. Wilbur, Kalamazoo, has been elected a member of the board of censors of the Kalamazoo Academy of Medicine, vice Dr. John H. McKibbin, removed from the city.——Dr. William A. Stone, Kalamazoo, has been elected to fill a vacaney in the board of censors of the Kalamazoo County Medical Society.——Dr. William J. O'Reilly has been elected president and Dr. Michael D. Ryan secretary of the medical staff of St. Mary's Hospital, Saginaw.

NEBRASKA.

Scarlet Fever Closes School.—The German school, 12 miles northwest of Beatrice, in Hanover Township, has been closed on account of the prevalence of a severe type of scarlet fever.

Personal.—Dr. Elias Holovtchiner, Omaha, has returned after a trip of three months in Europe.——Dr. Irwin C. Sutton, Shubert, will take two years of post-graduate work in Philadelphia and Europe.

Downs in the Toils.—Dr. Charles W. Downs, Omaha, was recently haled before the State Board of Health with having violated a statute by distributing pamphlets or other advertising matter detrimental to public morals. Dr. Downs pleaded ignorance of the law, and his case was allowed to go over until the September meeting.

Physicians Object to Law.—Omaha physicians are said to object to the provision of House Bill 63, requiring reports of contagious diseases to be made to the State Board of Health. The act makes it obligatory on attending physicians to file such reports with the board, at their own expense. The act imposes a penalty for each violation of its provisions. In addition the state board has adopted a rule requiring all these reports to be filed within twenty-four hours and all cases of smallpox, scarlet fever, diphtheria and meningitis to be quarantined not less than fourteen days and until such time as the case shall cease to be infectious. After the patient is released a release card must be filled out and sent to the board.

NEW YORK.

Milk Testing.—The monthly report of the state health department devotes much space to methods of testing milk intended for the use of infants.

Consumption Decreased.—It is reported that deaths from consumption in New York have decreased 40 per cent. since the health department began its crusade against the disease in 1891.

Lawton Hospital Opened.—Lawton Hospital, Herkimer, erected by Levi Lawton at a cost of $5,000, and equipped by other residents of the village at an expense of $3,000, was dedicated August 29.

Syracuse University Changes.—Drs. Tennyson L. Deavor, H. B. Doust and G. S. Doust have been made instructors in and demonstrators of anatomy; Dr. George A. Hanford is the new lecturer on chemistry and physiologic chemistry, and Dr. W. Dewey Alsever has been appointed instructor in physical diagnosis.

Deaths in Cities.—Vital statistics show the death rate in July to have been lowest in Ogdensburg, 9.4 per 1,000 and highest in Jamestown, 27 per 1,000. Of the larger cities Albany was highest (20.7), Rochester was lowest (15.7), with Syracuse (15.8), Buffalo (16.6), and New York (19.6). There were no cases of smallpox, though the average for five years has been 25.

Buffalo.

Personal.—Dr. Ernest Wende is on a fishing trip in Northern Canada.——Dr. Albert T. Lytle is taking a trip up the lakes.——Dr. James W. Putnam has returned from Prout's Neck, Me.——Dr. Edward L. Frost has returned from Muskoka.——Dr. Eugene A. Smith has resumed practice after an extended stay in the Adirondacks.

Adulterator Fined.—William Hipkiss, a milk dealer, pleaded guilty and was fined $50 and costs in the Municipal Court for putting formaldehyd in cream as a preservative. Mr. Hipkiss made an affidavit that the material used was bought under the name of "Special in Preservative" from the Preservative Manufacturing Company of New York. The State Department of Agriculture will investigate the matter mentioned in Hipkiss' affidavit.

New York City.

A Narrow Escape.—Dr. George G. Rambaud, director of the Pasteur Institute, and his wife had a very narrow escape from severe injury in a collision between their automobile and an electric car.

Free Antitoxin.—The health commissioner has asked for $70,000 for diphtheria antitoxin, and recommends that hereafter the sale of antitoxin by the department be stopped and that the preparation be furnished without expense to residents of the city.

Personal.—Dr. Edward H. Giles, while driving near Goshen, Mass., sustained a fracture of the arm and two ribs and a sprain of the hip in a runaway accident.——Dr. Frederick L. Flynn, house surgeon of St. Catherine's Hospital, Brooklyn, has resigned and has been succeeded by Dr. Lewis Schaefer.

PENNSYLVANIA.

Typhoid at Carbondale.—Up to noon, August 25, 47 cases of typhoid fever had been reported to the Carbondale Board of Health.

Staff Appointed.—Drs. Samuel C. Stewart, Francis G. Bennett and Bert E. Leipold have been appointed to the medical staff of the Clearfield Hospital.

Ambulance Struck by Locomotive.—While conveying a patient to the McKeesport Hospital, an ambulance was struck by a switch engine at Riverton and demolished; the ambulance surgeon was badly bruised, the driver thrown into the air and cut and bruised, but the patient escaped injury.

Pure Food Crusade.—August was a record-making month for the State Dairy and Food Department. About $6,500 was collected in fines for adulterations, and about 200 prosecutions were begun. About 100 dairymen of western Pennsylvania have recently been prosecuted and fined for putting formaldehyd in milk, the fines aggregating over $5,000. The president of a prominent brewing firm of Philadelphia is held in $500 bail on the charge of adulterating beer with salicylic acid. Several grocery firms when arraigned acknowledged selling adulterated goods, brandy, vinegar, lemon extract, etc.—though in some cases it was done ignorantly—and paid fines of $50 each and costs of court. The activity of the dairy and food commissioner is generally highly commended. Although the prosecution of firms selling impure articles in ignorance—sometimes under guarantee of their purity—seems a hardship, yet in the end it will perhaps prove an efficacious method of ridding the market of spurious goods and protecting the public from injurious and poisonous foods.

Philadelphia.

Memorial Services.—On August 30 memorial services were held in honor of John D. Laukenau, the benefactor and president of the German Hospital for so many years, the occasion being the third anniversary of his death. The board of trustees and other hospital officials and invited guests attended the service held in the hospital.

Instruction to Mothers.—Talks to mothers on the feeding and care of infants by members of the profession who volunteered to do so, are from time to time given under the auspices of the Bureau of Health. The plan seems the beginning of a practical method of instructing mothers in the essentials of the rearing of infants—a subject on which there is much gross, not to say criminal, ignorance.

Municipal Hospital Changes.—Dr. Jay F. Schamberg, on August 31, tendered to the Department of Health his resignation as assistant physician to the Municipal Hospital. Dr. B. Franklin Royer, on September 1, entered on his duties as chief resident physician of the hospital, thus dispensing with the necessity of an assistant physician. Dr. William M. Welch, who becomes consulting physician to the institution, is to receive a salary of $2,000 a year. Dr. Royer will receive a salary of $2,500 a year.

Much Typhoid.—A surprisingly large number of cases of typhoid fever are reported in the city. For the week ended August 29 there were 133 new cases, for the succeeding week 104. Officials are somewhat at a loss to account for the source of the contagion because some wards supplied with filtered water show the largest number of cases. The Bureau of Health is making especial study of the cases to determine the source of the infection.——Smallpox has decreased, there being 10 new cases for the last week of August, and 12 the following week.

Improved Milk Supply.—Much has recently been done and is now in progress to improve the milk supply of the city and state. Dairy and Food Commissioner Warren is carrying on an active warfare against impure foods, including milk. Additional city milk inspectors have been appointed and all are instructed to do their work thoroughly and carefully. The public has been invited to bring samples of milk to the Bureau of Health and to have them examined free of charge. Milk shops have been closed when they have failed to keep up to a proper standard of cleanliness.

To Stamp Out Smallpox.—More drastic measures have been adopted to stamp out smallpox. All cases of smallpox will be removed to the Municipal Hospital, none will be treated in their homes, as has sometimes been allowed. The inmates of the house in which a case occurs will also be sent to the Municipal Hospital for disinfection. While the latter is being accomplished the house will undergo fumigation, the effectiveness of the latter to be determined by a bacteriologic test. The entire process will take about 24 hours, after which those who have been exposed will be allowed to pursue their vocation, provided they have been successfully vaccinated. If vaccination is refused, quarantine will be imposed.

RHODE ISLAND.

Vanderbilt Waid Opened.—On August 1 the Newport Hospital received the new Vanderbilt ward, said to have cost $250,000. Other gifts from this family make the total received from them by the hospital over $500,000.

Diphtheria at Naval Station.—There are said to be about fifty cases of diphtheria at the naval training station at Harbor Island, and a number of cases developed on the *Monongahela* while she was out on a cruise for a month.

Another Glanders Death.—The third death from glanders in the state occurred in Warwick August 18. The patient contracted the disease from his horse, ill with the disease, which he was treating. The first lesion was an ulcer of the face near one eye.

TENNESSEE.

Released on Bond.—J. D. Alston, a colored physician of Nashville, arrested on the charge of criminal malpractice whereby the death of a young negress is alleged to have been caused, has been released on bonds of $3,000.

Health of Knoxville and Nashville.—In July 14 cases of smallpox and 2 cases of measles were reported in Knoxville. The death rate for the month was at the annual rate of 11.40, or nearly fifty per cent. less than for the preceding month. Tuberculosis led the death-causes.——In Nashville there were 182 deaths during the month, and 112 births were reported.

Personal.—Dr. S. Walter Woodyard has been appointed a member of the pension examining board at Greenville.——Dr. Oscar Copeland, Chattanooga, has returned after a tour of Europe.——Dr. Alfred S. Horsley, Knoxville, has been appointed division surgeon on the Mexican International Railway, with headquarters at Monclova.——Dr. and Mrs. Owen H. Wilson, Nashville, are in Japan.——Dr. D. T. Gould has been elected house surgeon of the Nashville City Hospital.

Vanderbilt Faculty Changes.—The medical department of Vanderbilt University, Nashville, announces the following changes in its faculty: Dr. George C. Savage has been made secretary of the faculty; Dr. George H. Price, professor of physiology and diseases of the eye, ear, nose and throat; Dr. Samuel S. Briggs succeeds Dr. A. Bennett Cooke as professor of anatomy; Dr. Owen H. Wilson has been made clinical professor of diseases of children; Dr. W. F. Clary, Jr., assistant to the chair of medicine; Dr. W. C. Dixon, assistant to the chair of gynecology; Dr. Albert W. Harris, assistant demonstrator of anatomy and assistant to the chair of abdominal surgery; Dr. William Litterer, assistant to the chair of materia medica and therapeutics, and demonstrator of histology and pathology.

TEXAS.

Appropriation for Post Hospital.—Authority has been granted for the construction of a hospital at Fort Bliss to cost $20,000.

Epileptic Colony Opens in October.—The state board of managers for the epileptic colony announces that the buildings will be completed and ready for the reception of patients about October 1.

Trouble Brewing.—Many physicians and midwives are ignoring the law passed by the last legislature providing that all

deaths and births be reported to the county clerk. The State Health Department announces that failure to comply with the law may be followed by prosecution.

Personal.—Dr. Benjamin F. Chambers, Palestine, who was recently assaulted and seriously injured, is making a good recovery.——Dr. Alva W. Carnes, Hutchins, physician at the Dallas County farm, is suffering from a dislocated shoulder and a fractured arm as the result of a runaway accident.—— Dr. H. C. McClanahan, Manor, has been appointed assistant superintendent of the Gardner Sanitarium, Belmont, Cal.

WISCONSIN.

Insanity Increases.—The report of the State Board of Control for the year ended June 30 shows that there were 197 more insane patients in the state than in the previous year, the respective aggregates being 5,372 and 5,175.

Tuberculosis Leads.—The death-causes in Wisconsin for the past year, in order, were as follows: Tuberculosis, pneumonia, organic heart disease, accident, kidney disease, gastroenteritis, cancer, typhoid fever, cerebral congestion, hemorrhage and diphtheria.

Appoints Tuberculosis Commission.—Governor La Follette has appointed a commission, consisting of Dr. Gustav Schmitt, Milwaukee, Prof. H. L. Russell, bacteriologist at the state university, Madison, and Dr. Michael Ravn, Merrill, whose duty it is to determine the advisability of the establishment of a state hospital for the treatment of tuberculosis in human beings.

Personal.—Dr. George Alfred Elliott, assistant physician at Lake Geneva Sanitarium, has resigned and has gone to Colorado on account of the ill health of his wife.——Dr. William J. Cronyn has been made professor of medical jurisprudence in Milwaukee Medical College.——Drs. Camillis E. Richards and William C. F. Witte, Milwaukee, have returned from Europe.

Right to Practice.—Dr. L. W. Zochert, Fond-du-Lac, has sued Dr. J. H. Blekking, Hingham, for the recovery of $1,000 on alleged breach of contract. The defendant, in consideration of $1,000 and $300 equity in property, is asserted to have given the plaintiff the entire field in the town of Hingham. A temporary injunction has been granted restraining Dr. Blekking from practicing medicine within an eight-mile radius of Hingham.

GENERAL.

Personal.—Dr. Archibald N. Sinclair has been appointed a member of the Board of Medical Examiners of the Territory of Hawaii, in place of Dr. C. L. Garvin, resigned.

Leprosy Scandal in Porto Rico.—The alarm caused concerning leprosy and the danger of its spread from the colony at San Juan has caused extensive investigation, which is expected to place the colony under proper conditions, and will result in the enforcement of regulations.

A Queer Coincidence.—In the obituary columns of this issue will be found the names of Drs. Thomas Palmer Wynn of Durham, N. C., and Alexander Montague Atherton of New York, and the same names appear under marriages. Dr. Wynn died from ptomain poisoning four days after his marriage and Dr. Atherton died from a throat trouble of long standing three days after he was married.

Yellow Fever Spreads in Mexico.—Yellow fever is reported to be spreading in the vicinity of Monterey, Tampico, Linares and Victoria, Mexico. In some places it is epidemic. The daily death rate is large. The Mexican Central Railroad has suspended operation between Monterey and Tampico by order of the Mexican government. Texas is enforcing her quarantine and endeavoring to exclude the disease.

Rumors of a Plague in Cuba.—Some epidemic of unknown nature but of great fatality was rumored to be raging in Daiquiri, an isolated town in the province of Santiago, Cuba, among men employed in the iron mines. The lay press has devoted columns and scare heads to it, but every authority they have thus far referred to has contradicted the rumors. The basis of the report is evidently the request sent to Columbia University and Jefferson Medical College for aid in diagnosis and treatment of malarial complications at the point mentioned. Dr. C. J. Finlay, chief of the Cuban Health Department, cables his denial of the exaggerated story and has sent Dr. Guiteras to Santiago to investigate.

The American Journal of Orthopedic Surgery.—The first number of this journal has just appeared. It is to be the official publication of the American Orthopedic Association. Its first issue is a handsome, well-illustrated number of over one hundred pages. The editorial committee consists of Drs. R. W. Lovett, Boston, B. E. MacKenzie, Toronto, and Harry M. Sherman, San Francisco. It will be published quarterly and replaces the Transactions, Vol. 1 of the Journal being Vol. XVI of the Transactions. If the contents of the first number are an indication of the permanent character of the Journal it certainly deserves the support of that portion of the profession that is interested in its special subject.

Government Wants Pure Milk.—The Agricultural Department, realizing the importance of the question of pure milk in the large cities, has issued a bulletin giving valuable suggestions with reference to the preparation and delivery of the supply. The bulletin calls attention to the fact that the ideal vessel for the conveyance of milk remains to be discovered. The following points are emphasized:

The registration of all dairies.
Official indorsement of properly conducted dairies.
Inspection of all herds, barns, dairy buildings, etc., once a month.
Better lighting, ventilation, drainage and cleanliness of cow stables.
Whitewashing the interior of stables.
Eradication of tuberculosis from dairy herds.
Branding of condemned cows.
Cows not to be given swill feed, etc.
Cows to be regularly cleaned.
Pasturage for city cows.
Delivery of milk and cream in sealed packages.

Increased Longevity.—The International Congress of Insurance Actuaries held its session in New York City. A prominent feature in the discussion was the admitted fact that people are longer lived now than formerly. This was attributed to the growth of hospitals, the advance in medicine and surgery and the more enlightened care of the poor and suffering, particularly the children. John K. Gore of Newark, N. J., presented statistics showing that during the last five years of the century there had been a very perceptible decrease in the mortality rate. From 1870-1874, the period including the fatal smallpox epidemic of 1872, there was an increase in the death rate at every age group but one. From 1880-1884, the rate was relatively high owing to the great prevalence and wide distribution of diphtheria, scarlet fever and measles. The influenza epidemic of 1891 caused an augmented death rate from 1890-1894. As to causes, it was stated that there had been a remarkable decrease from phthisis and a slight decrease from typhoid in the northern countries. Most of the other causes, affecting chiefly adult lives, show large increases.

The American Association of Obstetricians and Gynecologists will hold its sixteenth annual meeting in the Northwestern University Building, Dearborn and Lake streets, Chicago, Tuesday, to Thursday, Sept. 22-24, 1903. At 7:30 p. m. Wednesday the annual dinner will be served at the Auditorium Annex, at $3.00 a plate. Those who will attend should notify the secretary. The program is as follows:

TUESDAY, SEPTEMBER 22, 10 A. M.

Relationship of the Colon to Abdominal Tumors. Dr. James F. Baldwin, Columbus.
Ectopic Pregnancy. Dr. Henry D. Ingraham, Buffalo.
The Value of Vaginal Cesarean Section, with Report of a Case. Dr. Martin Stamm, Fremont.
The Limitations of Cesarean Section. Dr. E. Gustav Zinke, Cincinnati.
The Gilliam Operation. A Clinical Contribution. Dr. Edward J. Ill, Newark.
Hysteria as a Result of Chronic Atrophic Parametritis. A Contribution to the Study of Nervous Disturbances. Dr. W. A. Freund, Berlin.

TUESDAY, SEPTEMBER 22, 2:30 P. M.

Report of a Fourth Consecutive Successful Operation for Acute Perforated Gastric Ulcer with General Infection of the Peritoneal Cavity. Dr. Henry Howitt, Guelph.
Should the Uterus and Ovaries Be Removed in Operating for Double Pyosalpinx? Dr. Carlton C. Frederick, Buffalo.
The Technic of Gynecologic Operations and Treatment. Dr. Albert Vander Veer, Albany.
The Indications and Technic of Vaginal Drainage for Suppuration in the Pelvis. Dr. Albert Goldspohn, Chicago.
Shortening the Round Ligaments by the Blunt Hook Method. Dr. Howard W. Longyear, Detroit.
Extravaginal Elongation of the Cervix. Dr. Marcus Rosenwasser, Cleveland.
Report of Abdominal Sections During Pregnancy. Dr. Xavier O. Weber, Pittsburg.

TUESDAY, SEPTEMBER 22, 7:30 P. M.

Study of the Symptoms and Surgical Treatment of Intestinal Perforation in Typhoid Fever. Dr. W. D. Haggard, Nashville.
Rational Treatment of Postpartum Infection of the Uterus. Dr. D. Tod Gilliam, Columbus.
Conservative Surgical Treatment of the Uterine Adnexa. Dr. Augustus P. Clarke, Cambridge.
Traumatic Rupture of the Intestines without External Marks of Violence, with Report of Cases. Dr. George S. Peck, Youngstown.

Penetrating Gunshot and Stab Wounds of the Abdomen, with Report of Cases. Dr. John Young Brown, Jr., St. Louis.

WEDNESDAY, SEPTEMBER 23, 9:30 A. M.

Surgery of the Ileocecal Valve for Non-malignant Disease. Dr. N. Stone Scott, Cleveland.

Infantile Uterus, Scanty Menstruation, Amenorrhea and Dysmenorrhea Cured by Stem Pessaries. Dr. J. Henry Carstens, Detroit.

Tuberculosis of the Female Genitalia and Peritoneum. Dr. John B. Murphy, Chicago.

Appendicitis. Dr. Walter P. Manton, Detroit.

A Demonstration of Two Interesting Specimens, with Brief Histories. Dr. Xavier O. Werder, Pittsburg.

WEDNESDAY, SEPTEMBER 23, 12 M.

Memorial Address on the Life and Character of William E. B. Davis. Dr. Lewis S. McMurtry, Louisville.

President's Address. Dr. L. H. Dunning, Indianapolis.

WEDNESDAY, SEPTEMBER 23, 2:30 P. M.

The Choice of Methods for Closing the Abdominal Incision. Dr. Edward Ricketts, Cincinnati.

Cysts of the Kidney Resembling Ovarian Tumors, with Cases. Dr. Rufus B. Hall, Cincinnati.

Hysterectomy in Infectious Diseases of the Uterine Appendages. Dr. Harry C. Deaver, Philadelphia.

Supravaginal Amputation for Fibroid Tumors, with Report of Cases. Dr. H. E. Hayd, Buffalo.

The Scope and Limitation of Myomectomy in the Treatment of Fibroid Tumors of the Uterus. Dr. L. S. McMurtry, Louisville.

Coincident Tubal and Uterine Pregnancy, with the Report of a Case. Remarks. Dr. Frank F. Simpson, Pittsburg.

THURSDAY, SEPTEMBER 24, 10 A. M.

Symptomatology of the Pelvic Musculature. Dr. Hugo O. Pantzer, Indianapolis.

Palliative Treatment of Cancer of the Cervix. Dr. Walter B. Chase.

Abdominal Versus Vaginal Hysterectomy in Carcinoma Where the Radical Operation is Warranted. Dr. John B. Deaver, Philadelphia.

An Analysis of Common Causes of Death Following Pelvic and Abdominal Operations. Dr. Joseph Price, Philadelphia.

Total Extirpation of the Vagina for Carcinoma. Dr. Charles G. Cumston, Boston.

The Use of Veratrum Viride in Surgical and Obstetrical Practice. Dr. Charles L. Bonifield, Cincinnati.

THURSDAY, SEPTEMBER 24, 2:30 P. M.

Anesthesia in Abdominal Surgery. Dr. J. J. Gurney Williams, Philadelphia.

Further Preliminary Notes on Ovarian Grafting. Dr. Robert T. Morris, New York.

Clinical Demonstration of Special Points of Surgical Interest. Dr. John B. Murphy, Chicago.

Emergency Abdominal Surgery at the Patient's Home. A Demonstration. Dr. W. G. MacDonald, Albany.

FOREIGN.

Typhus in Bavaria.—Four hundred cases of typhus are reported in two regiments of the Bavarian infantry at Hammelburg, Bavaria.

Ismailia Free from Mosquitoes.—It is reported in London that as a result of the measures for the extermination of mosquitoes in Ismailia, malaria has dropped from 569 cases in the period January to May, 1902, to 72 in the same period for 1903. It is predicted that malaria will practically disappear. Mosquitoes are rare and mosquito netting is almost made unnecessary. Work is still progressing on filling up pools and preventing stagnant water.

Homage to a Physician in Frankfurt, Germany.—Dr. T. Neuburger has practiced medicine at Frankfurt a. M. nearly half a century, and the arrival of his fiftieth professional anniversary was celebrated by his friends by a gift of $19,000. He added to the sum and has set it apart as a permanent endowment for scientific medical research to be known by his name. His latest contribution to medical literature was an article on the connection between sclerosis of the coronary arteries and affections of the heart muscle.

Propagation of Giants.—A large legacy was left by Count Alfred St. Ouen de Pierrecourt to his native city of Rouen on condition that provision be made for propagating a race of giants. The natural heirs began litigation, which has now resulted in an agreement that the city shall found an institute for giants, keeping a large fund in reserve and giving the balance to the legitimate heirs. It is proposed to maintain a score or more of giant couples, establishing workshops for them and conditions favorable for scientists to observe the result of the progeny of giant couples. Dr. H. Meige of Paris published a protest against the idea some months ago, claiming that giant growth is pathologic. His remarks on the subject were reviewed in THE JOURNAL at the time, page 274 of the last volume.

Tragic Sequel to the Muehlhausen Contract Practice Trouble.—Our German exchanges have carried for many weeks a notice warning medical men not to enter into negotiations with the sickness insurance societies at Gera and Mühlhausen "without consulting the undersigned." Our readers will remember the resignations at these places of the medical officers of the sickness insurance societies on account of the prevailing intolerable conditions of the service. The warning ads were signed by the presidents of the district medical associations and by the president of the "Leipziger Verband." Dr. Schloss represented Mühlhausen. The cable now brings word of his death. It was at first ascribed to the results of a duel which he fought recently with the manager of the sickness insurance society, and the latter was arrested, but it has since been established that his death was due to sepsis after an operation. The state interfered in the matter of the medical attendance of the society, as was chronicled in THE JOURNAL at the time, the physicians practically gaining their point. The warning ad still appears in our German exchanges, but it refers only to Gera at present.

Physicians' Signs in Germany.—The latest decree of the Berlin Medical Court of Honor is directed against supernumerary signs hung out by physicians. It states that a single sign is enough, and any additional ones impinge on unethical advertising methods. The only exception is in case a physician resides in a corner house, when a sign on each of the streets is permissible. Proceedings were instituted against a Dr. Sternberg because he used more than one sign, and in his defense he cited another physician in Berlin who followed the same custom. The Court of Honor drew up a notice to the physician cited, warning him that he must restrict himself to a single sign, and published this notice in a Berlin daily paper. It concluded with the warning that if he did not comply with the specified order he would be summoned officially before the court. The *Allg. Med. Ct.-Ztg.* comments on the lack of tact shown in the publicity given to this notice, and adds that in the confusing multiplicity of street signs in a city a single, modest sign might easily be overlooked, and that it is for the interest of the public to have the physician's sign apparent, and if necessary to have more than one.

Increase of Heart Disease in Young Men in Germany.—The Prussian War Department has recently issued a pamphlet stating that the number of soldiers with heart disease amounted to 1.5 per 1,000 between 1885 and 1886. The proportion has gradually increased until the cases now number 3.1 per 1,000 of all the men in the service. In 1894 the proportion among the young men arriving at the age of military duty was 9.9 per 1,000, but in 1898 it had risen to 17.4 per 1,000. Kraus, Strickler and Landgraf have been studying the subject more closely, and Strickler does not hesitate to declare that the cause of this greater prevalence is the increasing degeneracy and nervousness of the youth of the land. Chronic valvular defects, he adds, exclude the subject from military service, but there are exceptionally functional heart disturbances which may allow military service, preferably in the cavalry or artillery. Special training of military medical officers in the diagnosis of heart diseases, both for treatment and for exclusion of "damaged recruits," will aid in reducing the percentage on the army list. In discussing the causes of the degeneracy of the youth to which he refers, he lays stress on the premature application of boys to arduous work, irregular hours of rest and work, deficient physical development, early use of alcohol and tobacco, sports in excess, especially bicycle riding, rowing and swimming, and dislike of physical exercise among certain classes. The frequency of hysteria and neurasthenia among the youth is also commented on, and the fact that these injurious factors may cause alterations in the heart muscle or merely an undue excitability and irritability. The acute diseases which have a special tendency to involve the vascular system have not increased in intensity or extent during the last twenty years, but the reappearance and prevalence of the grippe has evidently had a large share in the increased morbidity of the heart, either directly or by entailing prolonged weakness of the organ, rendering it less resistant.

LONDON LETTER.

The Declining Birth Rate of Australia.

The declining birth rate of native Americans, which has caused so much concern, is exactly parallel in Australia. Mr. Coghlan, the Australian statistician, has recently written on the subject. He points out that the fall in the birth rate in Australia and New Zealand taken together is such that there are annually fewer births by nearly 20,000 than would have occurred if the rates prevailing as late as ten years ago had been maintained. New South Wales furnishes a striking example. In 1887 there were in this state 112,247 married women under the age of 45; in 1901 there were 149,247, yet the number of children born was about the same in each year. The legitimate birth rate per 10,000 married women under the

age of 45 is 239; in 1891 it was 276. A curious fact is that the decline occurs in every class, among people of every shade of opinion, except among women of Irish birth, who exhibit no decline. But as the proportion of women of Irish birth is fast decreasing that element in maintenance of the birth rate will soon disappear. Large as is the area of the Australian continent Mr. Coghlan thinks it is impossible that its people will ever become truly great under the conditions affecting the increase of population which now exist. Immigration has practically ceased to be an important factor, the maintenance and increase of the population depending on the birth rate alone—a rate seriously diminished and still diminishing.

The Cancer Research Fund.

This organization is being developed on a wide basis, not only in the United Kingdom and the colonies, but also in cooperation with kindred organizations in America and on the Continent. The investigations fall mainly into three groups —experiments, therapeutics and statistics. It was deemed premature to give details of the experiments, but sufficient indications are given to show the value of the study of cancer throughout the animal kingdom and of attempts to facilitate early diagnosis. Although cancer research committees have been active in civilized countries for some time, little is known of its distribution in the lower races of mankind and still less in the lower animals. The necessity for securing farm accommodation where animals may be kept under observation is stated. Under therapeutics only the electric and light treatment is touched on. The beneficial action of the Röntgen rays in rodent ulcer is shown, but no similar results have been obtained in deep-seated growths, although in some cases relief of pain and temporary arrest of growth have been recorded. The lead of the German and other committees in reference to the questions of the increase of cancer contagion, cancer houses and cancer areas has not been followed. Such inquiry is regarded as futile until it can comprise differentiation of the various forms of cancer. An attempt is being made to compile statistics from the best available material—the records of the great hospitals in which the diagnosis has been verified by pathologic examination.

Trypanosomiasis Expedition from the Liverpool School of Tropical Medicine.

The Liverpool School of Tropical Medicine has decided to despatch next month a trypanosomiasis expedition to the Congo Free State. The expedition has been arranged with the co-operation of the government of the Congo Free State. The latter has contributed generously toward the expenses, which will be heavy. The objects of the expedition will be to report on the sanitary conditions of Boma, Leopoldville and other important centers and to make recommendations for their amelioration. Secondly, it will continue the work on trypanosomiasis, human and animal, commenced in the Gambia by Dr. Dutton in 1901, and continued for the past twelve months in the Gambia and Senegal by Dr. Dutton and Dr. Todd, including the occurrence and distribution of trypanosoma in the Congo, the carriers of the parasite and the relation of trypanosoma to sleeping sickness. As the investigations will involve the examination of the blood of wild animals, the Congo Free State is making arrangements for the expedition to participate in drives of big game up country and is facilitating their work in every possible manner. The expedition is under the charge of Dr. J. E. Dutton and consists of himself and Drs. J. L. Todd and C. Christy. Dr. Dutton was a member of the Southern and Northern Nigeria Expedition of the Liverpool School, 1899-1900, the leader of the Gambia expedition, 1901-1902, and of the Senegambia expedition, 1902-1903. Dr. Todd was a member of the latter expedition. Dr. Christy was a member of the commission of the Royal Society appointed to investigate sleeping sickness in Uganda and Central Africa, and has had a large tropical experience. Every facility for travel has been placed at the disposal of the school by Sir Alfred Jones, its chairman and munificent patron, whose interests in West Africa, commercial and philanthropic, are well known.

Correspondence.

Notes from Berlin.

BERLIN, August, 1903.

To the Editor:—Berlin is a sort of surgical heaven—at least for the surgeon. Where else shall one find so many masters teaching at one time as in and around the old Charité, fast being replaced by the new Charité. Professor König, 70 odd years young, operates every morning at 9:30, and what a ripeness of experience and sobriety of judgment are embodied in his work. Every afternoon at 2 Professor von Bergmann, surrounded by a white cloud of assistants, operates in the Langenbeckhaus. Both men are kindly, benignant and deliberate; both cut to the bone at the first stroke, if there is any bone; both use silk sutures and pour on iodoform by the spoonful. In both clinics the patient is usually anesthetized before the class, and often takes the anesthetic badly, and in both a nervous student not infrequently decorated with fresh facial cross-hatchings—how is it the professors rarely show a mark?—is invited into the arena to show how many things he doesn't know about the case in hand.

Beside these there are in surgery Krause, Israels and Sonenburg, and before speaking of other things, the closely allied chairs of pathology and anatomy. To hear Professor Waldeyer, another hale youth of 70 odd, describe the coquetries of the peritoneum at 7:30 a. m. is a treat for gods and men. Where shall one find such simple elegance of diction, such force through clearness, such restraint except when it comes to citing authorities? He resolves the multitudinous drape into its simplest elements and relations, he holds it up and spreads it out before you until it fairly beseeches you to retain and admire its every fold; a master truly. Difficult points are illustrated by specially prepared dissections and every facility which intelligent ingenuity can devise is brought into service for the student. If anatomy is the preface to surgery, pathology is too often the postscript. Not too rarely does the student see the cases he has watched in the clinic demonstrated in the department of Professor Orth, the able successor of Virchow. Here the autopsies begin at 7 a. m., and before the student leaves the building the lesions are demonstrated in detail by assistants. The principal organs, including the brain and long bones, are sectioned and assembled in another room and the microscopic structures are shown in a third. The rapidity and thoroughness with which everything of interest pertaining to each case is demonstrated is marvelous. So much can not be said of the valuable collection in the pathologic museum, which is closed to the public except for two hours on Sunday. It was opened to our party on presentation of cards to Professor Orth. The museum is specially rich in bones, and in complete skeletons of scoliotic and kyphotic individuals, but some of the cases stand in a poor light and the labels are written in a tiny blind chirography, which was in many instances undecipherable. If the labels were printed or written two or three times as large in a catalogue hand the value of the collection to the visitor would be doubled.

The dermatologists, Professors Lassar and Lesser, are great favorites of the students, not only from the importance of their subjects, but because both show many patients and are clear and interesting speakers; both hold daily clinics, the former in the Karl Strasse, the latter in the Charité. Professor Ohlhausen, who operates daily at 8 a. m. at the Frauenklinik in the Artillerie Strasse, impresses one at once as a man of originality, dexterity and force. He is a neat, rapid operator, never missing a stroke, and his methods are thoroughly modern. Professor Hoffa, recently transferred from Würzburg, has a beautifully equipped sanatorium in the Achenbach Strasse, where he does his private work. The public clinic on the other side of the city is also equipped with special apparatus for mobilizing joints and correcting deformities, with workshops and plaster and operating rooms. Tendon grafting is extensively practiced; the routine duration of the bloodless replacement and treatment of dislocated hips is about three months. Professor Joachinsthal also has an interesting clinic for deformities. The sanatorium of the late Dr. Beely is continued under his brother and Drs. Loff and Eckstein, and is especially notable for the variety of corrective apparatus for scoliosis. Dr. Eckstein has been doing high-grade work in the correction of facial and other deformities by the injection of melted paraffin. It was the writer's privilege to see several noses and an umbilical hernia treated by this method; the results were very gratifying. Dr. Eck-

stein believes that by using a paraffin of high melting point (58 C.) the dangers and disadvantages of vaselin and low-melting paraffin are very largely abolished.

His technic is simple and effective, the principal points being that the syringe and base of the needle are covered with rubber tubing, and a little hot water is drawn into the needle to prevent too rapid cooling. In conclusion, I would say that for the physician who understands German and who knows what he wants, the facilities for study in Berlin are exceptionally fine. HENRY LING TAYLOR.

New York address, 125 W. 58th Street.

Dissatisfaction with Medical Legislation.

SHELBYVILLE, IND., Sept. 5, 1903.

To the Editor:—In Chapter II, Article 1, Section 1, of the Principles of Medical Ethics, we find this clear and emphatic statement: "It is inconsistent with the principles of medical science, and it is incompatible with honorable standing in the profession, for physicians to designate their practice as based on an exclusive dogma or a sectarian system of medicine."

My son, after graduating in a regular school of medicine, went before the State Board of Examination and secured a certificate of competency signed by a physio-medical as president and an eclectic as secretary, who also advertised himself as a homeopath and a graduate of Pratt's School of Orificial Surgery.

Now, my son, as well as myself, feel very much humiliated when we are reminded that he is practicing medicine by the courtesy and under the certificate of two gentlemen who, according to the principles of medical ethics, have no *honorable standing* in the medical profession.

For this and various other reasons I have been dissatisfied with some of our recent medical legislation.

W. G. MCFADDEN.

Habits at Mineral Springs.

PARIS, ILL., Sept. 5, 1903.

To the Editor:—I wish to protest through THE JOURNAL against the practice of washing the drinking glasses used by consumptives, syphilitics, etc., in the soda spring at Manitou, Colo. I spoke to several parties while at Manitou, but some claimed that the ingredients of the water disinfected the glasses and others said that the spring was overflowing all the time and purified itself in that way. I have seen the water lowered two or three inches below the brink when there was a rush. I am told the bottling works use a different spring, which I hope is true. I am also told that the same filthy practice is followed at Waukesha, Wis., but I hope it is not so. W. H. TEN BROECK.

Marriages.

GEORGE R. GILBERT, M.D., Cumberland, Wyo., to Miss Dora C. Roys of Peru, Neb.

THOMAS PALMER WYNN, M.D., to Miss Alberta Robbins, both of Durham, N. C., August 19.

ALEXANDER S. MCCAIG, M.D., Sault Ste. Marie, Ont., to Miss Margaret Shanks of Mattawa, Ont., September 1.

JAMES G. POPE, M.D., Coleman, Texas, to Miss Virginia Joost of Tallahassee, Fla., at Palatine, Texas, August 30.

ALEXANDER MONTAGUE ATHERTON, M.D., of New York City, to Miss Ellen Louise Baker of Providence, R. I., August 25.

Deaths.

James Farquhar Hibberd, M.D., an esteemed member of the American Medical Association, of which he was president in 1894, died September 8 at his home in Richmond, Ind., after a long illness, aged 86 years. He was born at Monrovia, Md., Nov. 4, 1816, and received his academic education at Benjamin Hallowell's School, Alexandria, Va. Then, choosing the medical profession for his career, he read with his cousin Dr. Aaron Wright for one year, attended medical lectures in 1839 and 1840 at Yale University, and on Aug. 14, 1840, began practicing at Salem, Ohio. After seven years he went to New York and there took a two years' course at the College of Physicians and Surgeons, receiving his degree in 1849. He was at once made surgeon of the steamship *Senator*, sailing from New York to San Francisco, a voyage consuming seven and one-half months; thus Dr. Hibberd was made a "Forty-niner." He remained for six years in California practicing medicine and engaging in business with financial success. In 1855 he returned to the East and spent the winter in post-graduate study. In June, 1856, he opened an office at Dayton, Ohio, but four months later removed to Richmond, Ind. During the sessions of 1860 and 1861 he was professor of physiology and general pathology in the Ohio Medical College, Cincinnati. Early in his career he was one of the founders of the Ohio State Medical Society, and was later one of the chief organizers of the Indiana State Medical Society, and of the Wayne County Medical Society. He was a member of the American Medical Association since 1863, serving as its first vice-president in 1865. He was also a member of the Union District Medical Society, the Mississippi Valley Medical Association and Rocky Mountain Medical

JAMES FARQUHAR HIBBERD, M.D.

Association, in all of which societies he held official positions, and of most of which he was at one time president. He was an honorary member of the state medical societies of Ohio and California, and had been a member of the American Public Health Association for more than twenty years. In 1863, after the battle of Stone River, he was for some time in charge of the corps of volunteer surgeons and nurses at Murfreesboro, Tenn. In 1869 he went abroad for a year. During the years 1875 and 1876 he was mayor of Richmond, and in 1881 health officer of Wayne County. He was a member of the Ohio legislature in 1845, 1846 and 1847. In 1885 the University of Indiana conferred on him the degree of LL.D. In 1842 he was married to Nancy D. Higgins, who died four years later, leaving one son, who still survives; in 1856 he was married to Catherine Leeds, who died twelve years later, leaving one son, and three years later he was again married, to Elizabeth M. Laws.

George B. Russel, M.D. Jefferson Medical College, Philadelphia, 1836, who did heroic work in the cholera epidemics of 1836, 1844 and 1845 in Philadelphia; one of the pioneer physicians of Detroit; who influenced Mr. Harper and Nancy Martin to found Harper Hospital, and was the active medical head of that institution for a quarter of a century, died at his home in

Detroit, August 31, aged 87, a week after having been run down by a bicyclist.

Robert A. Patchin, M.D. University of Buffalo (N. Y.) 1869, a member and sometime president of the Polk County Medical Society; a member of the Iowa State Medical Society, Iowa State Association of Railway Surgeons, and International Association of Railway Surgeons, died at his home in Des Moines, Iowa, August 31, from an acute exacerbation of liver disease from which he had suffered for several years, aged 53.

Charles Brooks Brigham, M.D. Harvard University Medical School, Boston, 1870, surgeon during the Franco-German War, and Chevalier of the Legion of Honor for services there rendered; for many years surgeon of the Southern Pacific Railroad, died at his home in San Francisco, from apoplexy, August 23, after an illness of six weeks, aged 58.

Frank N. English, M.D. Chicago Homeopathic Medical College, 1886, of Mendota, committed suicide by severing the jugular vein and large arteries of the neck with a pocket knife, August 31, while under temporary confinement in the Mendota city jail on the charge of causing the death of a patient by a criminal operation. He was about 55 years old.

R. Henderson Graham, M.D. Columbus (Ohio) Medical College, 1879, a member of the Medical Association of the District of Columbia, the American Medical Association, and the American Therapeutic Society, died August 24, at Garfield Hospital, Washington, D. C., from peritonitis, which developed four days after an operation for appendicitis, aged 53.

Joseph A. Stout, M.D. Medical College of Ohio, Cincinnati, 1845, a pioneer of La Salle County, Ill.; one of the original abolitionists, and connected with the so-called "underground railroad," and a member of the American Medical Association, died at his home in Ottawa, August 25, after a long illness from paralysis, aged 85.

Charles Hart Boynton, M.D. Berkshire Medical College, Pittsfield, Mass., 1853, for two years president of the White Mountain Medical Society, and a member of the New Hampshire Medical Society, for two terms a member of the legislature, died at his home in Lisbon, August 16, from cerebral hemorrhage, aged 76.

George H. Cummings, M.D. College of Physicians and Surgeons, New York, 1875, for many years a member of the board of health of Portland, Maine, and also city physician, died suddenly from acute indigestion while on a yachting cruise near Booth Bay, Maine, August 22, aged 53.

Charles C. Lewis, M.D. University of Louisville, 1873, was found dead in his office in Owensboro, Ky., August 30, from angina pectoris, aged 54. He was vice-president of the Kentucky State Medical Society in 1902, and was a member of the Owensboro Board of Education.

William E. Allen, M.D. Albany (N. Y.) Medical College, 1856, an acting assistant surgeon during the Civil War, and health officer of Scranton, Pa., for many years, died from cancer of the bladder after a long illness, August 20, at his home in Scranton, Pa., aged 66.

William L. Northway, M.D. Chicago Homeopathic Medical College, 1879, of Marcellus, N. Y., died at the Hospital of the Good Shepherd, Syracuse, N. Y., from congestion of the brain, August 21, after an illness of two weeks, aged 51.

Edward C. Kearney, M.D. Western Reserve University, Cleveland, 1876, a member of the Allegheny County (Pa.) Medical Society, died at his home in McKeesport, August 31, from heart disease, after an illness of three hours, aged 59.

Newton Sager, M.D. Jefferson Medical College, Philadelphia, 1843, for sixty years a practitioner of Lafayette, Ohio, died at his home in that place, August 22, from cancer of the face, after a long period of suffering, aged 85.

Frederick A. Vigor, M.D. Columbus (Ohio) Medical College, 1879, of New Dover, Ohio, died at the home of his parents in Brandon, Ohio, August 24, from paralysis, after an illness of a year, aged 56.

Zachary Taylor Chrisman, M.D. University of Pennsylvania, Philadelphia, 1873, died at his home in Warwick, Pa., August 23, from Bright's disease, after an illness of about two years, aged 52.

Henry M. Hunter, M.D. College of Physicians and Surgeons, Baltimore, 1886, formerly of Union Springs, Ala., died at his home in San Luis, Potosi, Mexico, August 26, from pneumonia.

Robert D. Hudson, M.D. University of Pennsylvania, Philadelphia, 1879, formerly of Atchison, Kan., was found drowned in the Neosho river, near Emporia, Kan., August 24, aged 57.

Amadon Manley Piersons, M.D. New York Homeopathic Medical College and Hospital, 1868, died at his home in New York City, August 28, after a lingering illness, aged 65.

Joseph D. Casey, M.D. Jefferson Medical College, Philadelphia, 1892, died from paresis at his home in Latrobe, Pa., August 22, after an illness of several months, aged 33.

Lewis B. Ruhlman, M.D. Eclectic Medical Institute, Cincinnati, 1877, of North Lima, Ohio, died suddenly from heart disease in Youngstown, Ohio, August 24, aged 56.

Charles S. Stanley, M.D. Boston University School of Medicine, 1880, died from angina pectoris at his home in Amesbury, Mass., August 19, after a short illness, aged 64.

Thomas Palmer Wynn, M.D. University of Maryland, Baltimore, 1886, of Durham, N. C., died suddenly in New York City, August 23, from ptomain poisoning, aged 42.

Thomas Howard Wilson, M.D. University of Pennsylvania, Philadelphia, 1844, died at his home in Lewisburg, Pa., August 21, after a prolonged illness, aged 82.

Stephen C. Gillette, M.D. Rush Medical College, Chicago, 1852, a member of the Fox River Valley Medical Association, died at his home in Aurora, Ill., September 3.

John Bostwick Lundy, M.D. University of Buffalo (N. Y.), 1851, died at his home in Preston, Ont., from paralysis, August 20, after an illness of one week, aged 77.

Harvey K. Leonard, M.D. Hahnemann Medical College, Philadelphia, 1881, died suddenly from heart disease at his home in Plymouth, Pa., August 23, aged 49.

Dean Seaman, M.D. Jefferson Medical College, Philadelphia, 1879, was found dead in bed at his home in Beaver Dams, N. Y., August 22, from apoplexy, aged 47.

Theodore A. Collett, M.D. University of Michigan, Ann Arbor, 1867, a pioneer physician of Iowa, died at his home in Ida Grove, August 27, from apoplexy.

Jesse C. Hancock, M.D. Miami Medical College, Cincinnati, 1866, the oldest physician in Trimble County, Ky., died at his home in Bedford, August 23.

Edmund Y. Meyer, M.D. Missouri Medical College, St. Louis, 1887, died at the City Hospital, St. Louis, from acute alcoholism, August 30, aged 39.

Barton K. Mynatt, M.D. University of Nashville, 1854, died suddenly at his home in Washington, Tenn., August 29, from heart disease, aged 78.

John S. Wentz, M.D. University of Pennsylvania, Philadelphia, 1855, died at his home in Drifton, Pa., August 28, from paralysis, aged 75.

Thomas A. Ablett, M.D. Cleveland Homeopathic Medical College, 1895, died from diabetes, August 7, at his home in Glennie, Mich., aged 35.

James M. Blair, M.D. Transylvania University, Lexington, Ky., 1849, died at his home in Corsicana, Texas, August 13, aged 86.

Charles Howard Gordon, M.D., 1876, died at his home in Lodi, Cal., August 24, from diabetes, after a long illness, aged 71.

David B. Cotton, M.D. Jefferson Medical College, Philadelphia, 1856, died at his home in Portsmouth, Ohio, August 30, aged 70.

Alexander Montague Atherton, M.D. Johns Hopkins University, Baltimore, 1901, died at Liberty, New York, August 28, aged 28.

George C. Dugas, M.D. Medical College of Georgia, Augusta, 1878, died suddenly at Augusta, Ga., August 28, aged about 50.

Oliver E. Tillson, M.D. Eclectic Medical Institute, Cincinnati, 1862, died at his home in West Alexandria, Ohio, August 28.

David Wolf, M.D. Eclectic Medical Institute, Cincinnati, 1852, died recently at his home in West Alexandria, Ohio.

Benjamin W. Sparks, M.D. New York University, 1859, died at his home in McMinnville, Tenn., August 29, aged 67.

Stephen R. Mason, M.D. Rush Medical College, Chicago, 1851, died at his home in Devall Bluff, Ark., August 20.

Samuel W. Chandler, M.D. University of Michigan, Ann Arbor, 1872, died recently at his home in Saline, Mich.

W. H. Morris, M.D. Missouri Medical College, St. Louis, 1866, died at his home in Sharon, Mo., August 2.

William A. Jones, M.D., died at his home in Sturgis, Ky., August 18, from paralysis, aged 70.

Frank C. Fraser, M.D. McGill University, Montreal, 1898, died recently in Montreal.

Joseph E. Kirkley, M.D., died at his home in Beckville, Texas, August 15.

Deaths Abroad.

William E. Salazar, College of Physicians and Surgeons, New York, of Havana, Cuba, physician in charge of the American Hospital at Tampico, Mexico, died recently at Tampico from yellow fever, aged 29.

George William Balfour, M.D. St. Andrews, 1845; F.R.C.P. Edinburgh, 1861, one of the most celebrated physicians and teachers of the Edinburgh Medical School, died recently, aged 81. His principal work was done on the diseases of the heart. Among his published works were "An Introduction to the Study of Medicine," "Clinical Lectures on Diseases of the Heart," and "The Senile Heart." As a young man he had the courage and originality to promulgate the heresy that the routine treatment of pneumonia by antimony and blood-letting was unnecessary and harmful. He was a member of the Royal Medical, Medico-Chirurgical and Obstetrical societies and consulting and attending physician to many hospitals.

Book Notices.

ORGANIC NERVOUS DISEASES. By M. Allen Starr, M.D., Ph.D., LL.D., Professor of Diseases of the Mind and Nervous System, College of Physicians and Surgeons. Illustrated with 275 Engravings in the Text and 26 Plates in Colors and Monochrome. Cloth. Pp. 751. Price, $6.00 net. New York and Philadelphia: Lea Brothers & Co. 1903.

As the title indicates, this book treats of only the organic nervous diseases. So-called functional diseases, such as epilepsy, hysteria, paralysis agitans, etc., are not considered, nor are trophic disturbances, as acromegaly, and Raynaud's disease. The opening chapter is a discussion of the structure of the nervous system based on the neuron hypothesis. One hundred and thirty-four pages are devoted to the peripheral nerves, and about one-half of these to the various forms of multiple neuritis, which are discussed in a thorough manner and illustrated by a number of the author's cases. Diseases of the spinal cord are given 236 pages. The chapter on the diagnosis and localization of spinal cord diseases demonstrates clearly how careful observation of signs and symptoms will enable a physician, equipped with a knowledge of the anatomy and physiology of the cord, to make an accurate diagnosis by a more logical process than in any other class of diseases. The remaining 320 pages are devoted to diseases of the brain, including an exhaustive chapter on localization and general diagnosis. As stated by the author, his conclusions are largely based on clinical and pathologic data collected by himself in twenty years of neurologic practice. Hence, we are not only presented with old facts in a new and improved form, but offered new observations and suggestions in connection with nearly every subject treated. Illustrative cases from the author's practice are frequently narrated. Where divergent views are held, they are fairly stated. Thus, after stating the present opposing views concerning the nature of the regeneration in severed nerve fibers he suggests that the process may vary, according to the stage of degeneration reached; if advanced, healing must proceed from the proximal stump; if not advanced, it may take place from the neurilemma of the peripheral end. It is an interesting suggestion that many cases of multiple neuritis following infectious diseases, such as typhoid fever and pneumonia, or appearing in the course of tuberculosis, are caused by the alcohol used in the treatment of the primary disease. Another plausible suggestion is that most cases of so-called acute myelitis, particularly those of very sudden onset, really are instances of softening due to vascular disease. The statement that brachial neuritis is fully as frequent as sciatica may not be generally accepted by clinicians. Pathologists will hardly accept the statements that cerebral emboli may be derived from thrombi in the saphenous veins (except in the case of an open foramen ovale, which is not mentioned), that tumors of the pituitary body are usually of the nature of fibroma or myxoma, and that the chalky plaques frequently seen in the arachnoid are beginning psammomata. They will claim that carcinoma of the vertebræ is always secondary, not merely "usually" so. It is stated as a fact that general paralysis begins with changes in the vessels. Bacteriologists will feel strangers to the *Streptococcus aureus*, and will give to the pneumococcus a relatively more important place in the etiology of meningitis than the author has done. The following statements sound peculiar: "Solitary tubercles are occasionally found throughout the cord," and "Retention of urine is liable to set up catarrhal conditions, and finally cystitis." The term "neuron" is used in some places to indicate both cell and axon, in others the cell alone. It is deplorable that the author will aid to perpetuate the ambiguous term "dorsal" instead of "thoracic" region of the spine and cord. The term "acute progressive paralysis" for Landry's paralysis, though in itself a good one, must be condemned, as "progressive paralysis" is now commonly used to designate general paralysis of the insane. However, a few defects must be expected in a book which is so strikingly one man's work. The personality of the author is felt on every page, though other authorities are freely quoted and references given in foot notes. The work deserves special commendation for the pains taken in pointing out underlying pathologic conditions and the logical necessity of their producing certain definite symptoms. The subject of treatment is by no means neglected. Thus, eight pages are devoted to the treatment of tabes, and seven to that of apoplexy. After pointing out that it is not possible to arrive at a positive diagnosis between a clot and softening in more than one-half of the cases he adds: "When it is impossible to make an accurate diagnosis between hemorrhage and thrombosis or embolism it is not safe to employ active medication directed to either condition lest the damage to the brain may be increased." And speaking of the use of potassium iodid to absorb a clot, he says: "Those who believe it will accomplish any result may continue to use it." The illustrations are abundant and uniformly excellent. Some are original, though most of them have been borrowed. Those in the recent work of Schmaus and Sacki on the pathology of the spinal cord have been heavily drawn on and well reproduced.

DISEASE OF THE PANCREAS. Its Cause and Nature. By Eugene L. Opie, M.D., Associate in Pathology in the Johns Hopkins University. Cloth. Pp. 359. Price, $3.00. Philadelphia and London: J. B. Lippincott Company. 1903.

This book is a good example of what all will agree is the most desirable kind of medical literature in this country in which medical book publishers issue almost exclusively books that are fairly certain to have a respectable sale, such as textbooks of all kinds, large and small, compends, etc. Of course we can not expect medical publishers to become so philanthropic that they will publish many medical books at financial loss, simply because they are good books, but it is most desirable that the facilities for the publication of monographs and books dealing exhaustively with limited subjects be encouraged. Perhaps the best way to persuade the publishers of the desirability of this innovation is, first, to offer for publication really first-class material, and, secondly, when books like Opie's Diseases of Pancreas are published to help increase the sales. In this particular instance the qualities of the book, the amount of important, original work of direct interest to the physician and surgeon, that is set forth in a simple yet delightful style, are bound to secure for the book many readers. The contents are of interest alike to the physician and surgeon. To quote from the preface: "The recognition of pancreatic lesions, their causes and their consequences, is of great importance, not only to the physician, but notably to the surgeon who opens the abdomen. For illustration, disseminated fat necrosis indicates grave disease of the gland; acute pancreatitis is a not infrequent consequence of cholelithiasis; while chronic pancreatitis, which accompanies the same condition, is frequently mistaken for malignant growth. To the student of internal medicine few conditions

present greater difficulties of diagnosis than do the various forms of pancreatic disease; but with increasing knowledge of their etiology, their nature, and their relation to other diseases, means for their recognition are closer to hand." Of the contents may be mentioned chapters on the anatomy of the pancreas, the anomalies, the microscopic anatomy, including the islands of Langerhans; varieties of acute pancreatitis, the etiologic relation of gallstones to acute hemorrhagic pancreatitis, fat necrosis, chronic interstitial pancreatitis, its varieties and etiology; diabetes mellitus and its relation to lesions of the pancreas; bronzed diabetes; the symptoms and treatment of pancreatic disease. The illustrations are helpful and tasteful; there are interesting reproductions of the original drawings of Santonini, showing both ducts of the pancreas and the papillæ in the duodenum; the principal lesions are well illustrated. Opie's book is a most important addition to the literature of the pancreas and its diseases, and should be found in the library of every progressive physician and surgeon. The amount and quality of new, original work here set forth has advanced greatly our knowledge of the pancreas and its diseases, and the book will always be a landmark in the history of the pancreas.

Miscellany.

Discussion of Appendicitis—A Correction.—Dr. Miles F. Porter calls attention to the fact that remarks were erroneously credited to him in the discussion on the paper of Dr. Gibbons in THE JOURNAL, August 29, page 546. The sentences that are credited to Dr. Porter were made by Dr. Ochsner in reply to Dr. Porter's question.

Tongue Reaction to Mercury in Latent Syphilis.—Baroch adds his testimony to that of Herxheimer and Krause in regard to the diagnostic value of the reaction that follows the first dose of mercury, if it is a large one. The two latter observed a reaction in the cutaneous lesions, but Baroch has noticed it on the tongue. The reaction is apparent in fifteen to twenty hours and disappears after twenty-four to forty-eight. It is sometimes accompanied by a temperature reaction. In five cases he found the opaline patches on the tongue, the reaction to the mercury, in less than twenty hours after inunction of about 10 gm. of gray ointment.—*Allg. Med. Ct.-Ztg.*, lxxii, p. 133.

State Boards of Registration.

Oregon Report.—Dr. Byron E. Miller, secretary of the Board of Medical Examiners of the State of Oregon, reports the examination held at Portland, July 7 to 9, 1903, as follows: Number of subjects examined in, 15; total questions, 100; percentage required to pass, 75 per cent.; written examination; total number examined, 24; passed, 20; failed, 4.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE CAUSE OF CANCER.

CATHLAMET, WASH., Aug. 17, 1903.

To the Editor:—Has the parasitic theory as to the origin of cancer been fully established? Has Roswell Park, or any other investigator, clearly demonstrated that any one parasite is constantly present? What are the latest ideas of our best pathologists on this subject? Kindly answer through THE JOURNAL.

C. W. B.

ANS.—The parasitic theory has not been established. No one has demonstrated the constant presence in cancer of undoubted parasites, and no one parasite has been shown to be associated always with any special form of cancer. The "best pathologists," we believe, are skeptical as to the correctness of the claims put forward now and again by the advocates of the parasitic theory. The problem is unsolved, and we must be content for the present to regard the cause of cancer as wholly unknown.

REPORT ON THE SCIENTIFIC EXHIBIT

Of the American Medical Association, at New Orleans, May 5-8, 1903.

By Frank B. Wynn, A.M., M.D., Chairman.

(Concluded from page 623.)

MEDICAL DEPARTMENT, UNIVERSITY OF INDIANAPOLIS: FRANK B. WYNN AND JOHN S. WRIGHT.

Research Group.

No. 318. Banana Shreds of Fibrovascular Tissue, passed in stool and supposed to be parasites. This was reported to the Indianapolis Medical Society in 1901 by F. B. Wynn, and is the third such submitted to him for identification.

No. 319. Segments of Cabbage, probably served as slaw, passed in the stool, and supposed to be tapeworm. The resemblance to segments of the tapeworm was striking, but the microscope easily revealed the vegetable nature of the product.

No. 320. Ribbons and Shreds of Paper Passed in Stool.—Some portions resembling the segments of tapeworm; others were like the mucous casts occurring in mucous colitis. The woody fiber of many papers makes them very indigestible. They may be so intimately adherent to such things as meat, caramel candy, etc., as to escape notice, and in the stool might easily give rise to error in diagnosis.

No. 321. Fusiform Masses of Parenchyma Cells of the Lemon, passed in the stool and mistaken for parasites. The resemblance to the fluke is striking.

The foregoing specimens led to an experimental study by ten students of the university designed to show the following:

(*a*) The histology of common fruits and vegetables used as articles of diet, including apple, peach, pineapple, pear, banana, gooseberry, currant, rhubarb, grape, tomato, string bean, navy bean, onion, sugar corn, pop corn, celery, Irish and sweet potato, peanut, cabbage, kale and cucumber.

(*b*) Effect of the ordinary methods of preparing food for table use in causing disintegration. In an assigned article the student made fresh mounts from the food as found on the table at the restaurant.

(*c*) Effect of digestive processes on these foodstuffs and the recognition of partially altered food remnants which might be mistaken for parasites. Each student ate freely of an assigned article at different times, afterward searching the stools for remanants of the food taken.

These studies demonstrated very clearly that the fibrovascular tissue, especially of pineapple, rhubarb and celery, often resists the action both of cooking and the digestive juices, appearing as slender white threads in the stools, which might easily be mistaken for worms.

Nos. 322-376. Drawings and Gross Specimens Illustrative of the Foregoing.

Miscellaneous Group.

Nos. 377-382. Pulmonary Tuberculosis, Different Types.
Nos. 383-388. Liver Series.
Nos. 389-394. Kidney Series.
Nos. 395-405. Embryologic Series.
Nos. 406-411. Miscellaneous Specimens.

These were all Kaiserling preparations mounted in glycerin jelly by students of the university. The mounting was unique and artistic. The containers were Petri dishes set in heavy oak boards, which are convenient for class demonstration, non-breakable and may be stacked in drawers away from the light—a factor of importance in preserving the colors.

RUSH MEDICAL COLLEGE: E. R. LE COUNT.

Experimental Group.

Nos. 412-415. Series of Preparations Illustrating Experimental Fat Necrosis, as obtained by injecting either commercial pancreatins or extracts of fresh hog pancreas into the abdominal cavity of dogs and cats. The specimens showed the results respectively twenty-five hours, forty-eight hours, five days and nine days after injection. (See article by Wells, *Journal Medical Research,* 1903, iv, 70.)

No. 416. Gangrenous Pancreatitis with Disseminated Fat Necrosis.—This specimen was shown for purposes of comparison with the experimental lesions. The foci of fat necrosis were visible over the mesentery and omentum. At the necropsy the head of the pancreas was found to be of normal firmness, with distinct lobular markings on the cut surface and gray with reddish mottling foci. Necrosis of the entire body of the pancreas had taken place.

No. 417. Subacute Hemorrhagic Pancreatitis, with Fat Necrosis.—Specimen from a man who died of lobar pneumonia. Dark red areas, irregular in outline, were seen externally in the fresh specimen; also yellow areas. Histologic examination showed an acute inflammation in addition to extensive necrosis and hemorrhage.

Group of Heart Specimens.

Nos. 418-423. Series of Cardiac Anomalies.—These included asymmetrical pulmonary segments; fenestrated foramen ovale; perforate ventricular septum, and a rare congenital mal-development in which there was communication between the aorta and left ventricle under the base of the anterior aortic valve. Hektoen could find no mention of a similar case in literature.

Nos. 424-435. Series of Endocardial Heart Lesions.—Three of these were of acute aortic endocarditis; three of acute mitral or parietal endocarditis, and six were chronic valvular deformities resulting from fibrosis or calcareous infiltration, causing stenosis or insufficiency.

Group of Miscellaneous Specimens.

No. 436. Skeleton of a Short-Limbed Dwarf.—From a man 45 years of age. There was a fibroid thyroid, containing no demonstrable thyroidin(?). The cranial vault possesses 172 wormian bones. The skeleton has some features of osteogenesis imperfecta and some of chondrodystrophia fetalis. The absence of a clinical record and the disuse incident to deformity, with resulting alterations of the bones, are factors which make classification difficult.

No. 437. Acute Yellow Atrophy.—The hepatic tissue illustrating this rare disease was from a woman 35 years of age. She had jaundice in August, and when admitted to the hospital the following November the icterus was very deep and she had been semi-stuperous for several days. Death occurred twenty-four hours after admission. Only partial examination was permitted. In the specimen large reddish areas were noted which contained very little liver tissue; greenish districts still showed some lobular markings.

Nos. 438-439. Rupture of Spleen.—In one of these, by the passing of a wagon wheel over the body, the organ was torn in two pieces. Operation in six hours was followed in a month by complete recovery. The other was a crushing injury from an elevator. Operation in eight hours, with complete recovery. In one there was subsequent glandular enlargement.

Nos. 440-452. Miscellaneous Gross Specimens.

The instructiveness of this fine collection was greatly enhanced by very complete accompanying data—clinical and pathologic—plainly written on white paper.

JOHNS HOPKINS UNIVERSITY: HARRY T. MARSHALL AND T. S. CULLEN.

Internal Medicine Group.

These were designed to illuminate more particularly amebic dysentery, a topic prominently considered in the Section on Practice of Medicine.

Nos. 453-456. Amebic Dysentery.—These specimens showed very typically the intestinal lesions.

Nos. 457-460. Amebic Liver Abscess.

Nos. 461-464. Intestinal Lesions of Typhoid.

Nos. 465-468. Tuberculous Ulcers of the Intestine.—The typhoid and tuberculous lesions of the intestines were exhibited for purposes of differentiation from dysenteric lesions.

Gynecologic Group.

These were limited to uterine myomata and represented the cullings of material obtained at the Johns Hopkins Hospital. The specimens and drawings were used in illuminating a paper read by T. S. Cullen before the Section on Obstetrics and Diseases of Women.

No. 469. Myoma Showing Sarcomatous Nodules in Middle.

No. 470. Specimen Showing Transition of Myomatous Fibers into Sarcoma.

No. 471. Diffuse Adenomyoma, occupying inner layers of uterus and forming a complete zone around the uterine cavity. Histologic examination showed that the gland elements were derived entirely from the mucosa.

No. 472. Early Adenocarcinoma of Body Associated with Myoma.—The growth was so recent that the mucosa was not in the least thickened.

Nos. 473-478. Cervical and Submucous Myomata.

Nos. 479-496. Myomata Showing Various Degenrative Changes.

Nos. 497-568. Drawings Made from Sections of the Foregoing Tumors.

These two very complete groups of specimens were contributed in conformity with the wishes of the committee, aiming thus to illuminate subjects of prominence considered on the section programs.

MEDICAL DEPARTMENT, WASHINGTON UNIVERSITY: WILLARD BARTLETT.

Experimental Group.

Nos. 569-577. Experimental Intestinal Anastomosis.—These specimens were obtained from dogs, and are used for teaching purposes

in the university. They were beautifully prepared and showed well the following:

(*a*) End-to-end anastomosis, Connell suture, 30 hours. Illustrating too long a diaphragm.

(*b*) End-to-end anastomosis, Halstead peritoneal suture, 5 days. Too long a diaphragm.

(*c*) End-to-end anastomosis, Connell suture, 16 days. Illustrating the small diaphragm which should be present at this time.

(*d*) End-to-end anastomosis, Connell suture, 40 days. Almost complete disappearance of diaphragm, and re-establishment of normal lumen.

(*e*) Lateral anastomosis, Halstead peritoneal suture, 21 days. Showing the growing together of new opening.

(*f*) Lateral anastomosis, Halstead peritoneal suture, four Connell through-and-through sutures added 21 days. Opening prevented from growing together by last-named sutures.

(*g*) Lateral anastomosis, Halstead peritoneal sutures, 28 days. Showing new opening more grown together than in (*e*).

(*h*) Lateral anastomosis, two rows of continuous Lembert sutures, one through peritoneum and other through all coats of bowel, 49 days.

(*i*) Lateral anastomosis, Halstead peritoneal suture, 87 days. Illustrating a new opening so grown together that there is distension of the proximal loop in consequence.

Miscellaneous Group.

Nos. 579-585. Miscellaneous Gross Specimens.

ST. LOUIS UNIVERSITY: WILLARD BARTLETT.

Nos. 578-585. Miscellaneous Gross Specimens.

These were all prepared by the Kaiserling method and illustrated various pathologic points well. Metastatic sarcoma was beautifully shown in the lung, liver, kidney and spleen.

COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO: W. T. ECKLEY.

Nos. 596 621. Anatomic Specimens.

Nos. 622-633. Gross Pathologic Specimens.

The first set was beautifully prepared, semi-moist specimens used by the exhibitor in teaching in the college. Accompanying these was a batch of theses by students, containing a large number of original drawings, testifying forcefully to the excellent work done in the institution in this department. This is the third successive year in which this institution has contributed ably toward the Scientific Exhibit of the Association.

ST. PETER STATE HOSPITAL, MINNESOTA: H. D. VALIN.

Nos. 634-648. Casts of Pathologic Brains.—Illustrating the following pathologic conditions: Porencephaly, glioma, amniotic adhesion band, destruction of cortex, localized internal hydrocephalus and hematoma duræ. (Made in the laboratories of the institution.)

Nos. 649-658. Surface Anomalies of Convolutions and Sulci.

Nos. 659-664. Anatomic Casts of Brain and Cord.

Nos. 665-779. Album of Photomicrographs.—The first sixteen were of the brain cortex of the cat and rat, showing, by way of comparison, sections before and after the various stages of fatigue. The remainder were of various pathologic conditions of the central nervous system, including acute delirium; first, second and last stages of degeneration in cells; capillary hemorrhages into the brain cortex; asphyxia in epilepsy; multiple embolism (luetic); hemiatrophy and hemisoftening, diseased and healthy sides; atrophy of auditory cortical center compared with opposite side; senile and manic-dementia, with degeneration of cortex; sclerosis of comma tract in general paresis; tumor of pituitary; glioma; tumor of spinal cord, and many others.

Nos. 780-815. Lantern Slides of the Foregoing.

The photomicrographs were artistic in showing the utmost detail of histologic structure and were made doubly interesting by the very complete and methodical, clinical and pathologic data which accompanied them.

COOK COUNTY HOSPITAL, CHICAGO: F. G. HARRIS.

The following collection consisted of choice Kaiserling preparations. Some were of unusual pathologic as well as clinical interest. It is creditable to the institution to have made such a contribution.

No. 816. Ileum Showing Attached Hookworms.—These specimens of *Uncinaria americana* were from a man aged 52 years who had lived in Panama for twenty-five years. For a year and a half previous to death he suffered from severe progressive anemia. The eggs and larvæ were found in the stools. Blood examination gave the following: Reds, 846,000; whites, 4,500; hemoglobin, 12 per cent.; eosinophiles, 13 per cent.; no nucleated reds. (Reported by Copps, THE JOURNAL A. M. A., January, 1903.)

No. 817. Charcot Knee Joint.—The specimen showed beautifully the destruction of the ligaments, cartilages and synovial membranes; also the erosion of the bones and periarticular fibrosis. The patient was a man who contracted syphilis fifteen years previously. For two years he noted a progressive and painless enlargement of the joint. Excessive mobility interfered with locomotion. Other symptoms and signs of tabes dorsalis present.

No. 818. Puerperal Endometritis-Infection with Bacillus Aerogenes Capsulatus.—Specimen obtained from a woman 24 years of age, confined three days before death. Gas containing cavities were to be seen throughout the uterus.

No. 819. Mycloma of Femur.—Circumference of knee, 28 inches. Tumor transparent to *x*-rays. The patient, a woman of 30, received an injury to the knee seven years ago. Six months later progressive enlargement of the knee began and was accompanied by some pain and limitation of motion. No metastases.

No. 820. Congenital Cystic Kidney.

No. 821. Bilateral Cystic Kidneys.

No. 822. Unresolved Pneumonia.

No. 823. Aneurism of Thoracic Aorta.

No. 824. Aneurism of Abdominal Aorta.

No. 825. False Aneurism of Abdominal Aorta.

No. 826. Serofibrinous Pericarditis.

No. 827. Adhesive Pericarditis.

No. 828. Atrophic Cirrhosis of Liver.

No. 829. Metastatic Carcinoma Lungs.

No. 830. Metastatic Carcinoma Liver.

No. 831. Splenic Cyst.

No. 832. Interstitial Carcinoma Stomach.

The following series of specimens was entirely in illustration of the gross lesions of malaria.

U. S. ARMY MEDICAL MUSEUM, WASHINGTON, D. C.: COL. CALVIN DE WITT.

No. 833. Spleen and Kidney in Chronic Malarial Poisoning.

No. 834. Darkly Congested Kidney, Pernicious Malarial Fever.—Estivo-autumnal parasite found in spleen. H. E. N., aged 23, white. Admitted March 2, 1900, to Post Hospital, Cebu, Philippine Islands; April 15 was outdoors and exposed to sun; fainted, and blood appeared in urine and feces. On the 18th and 19th there was much restlessness and prostration; unconsciousness; intense yellowishness of skin and conjunctiva; persistent vomiting; involuntary urination and defecation; heart action weak; constantly under strychnia stimulation. Repeated peripheral examination of blood failed to show malarial parasite. Urine blackish and contained vast numbers of partly disintegrated blood corpuscles and blood casts; little albumin; no epithelium or casts; color much improved during last twenty hours of life. Died 19th. Necropsy three hours after death. Lungs apparently normal; liver a muddy color; gall bladder contained a thick, tarry bile; small intestine much stained with bile and contained twelve lumbricoid worms; kidneys darkly congested; spleen much enlarged, dark and congested; scrapings from latter showed microscopically the estivo-autumnal parasites, containing large pigment granules in active motion.

Nos. 835-836. Spleen and Kidney in Pernicious Malarial Fever.—From the Philippines.

No. 837. Spleen in Chronic Malaria.—From the Philippines.

This special series was solicited by the Committee. It makes the second time that the Army Medical Museum has contributed liberally, under the direction of Col. DeWitt, to the Scientific Exhibit of the Association.

The Indiana State Medical Association was the first organization to institute the scientific exhibit as a feature of society work, and to its efforts may be attributed the introduction of the exhibit into the American Medical Association. The collection was entirely of dry specimens.

INDIANA STATE MEDICAL ASSOCIATION: FRANK B. WYNN.

No. 838. Skull Trephined by Baron Larrey, surgeon of Napoleon I. During the retreat from Moscow in 1812 the man was cut down by a Russian cossack and left on the field twenty-four hours. He recovered after trephining, and continued in the service a year. Died in 1873. Just above the squamous portion of the temporal is a quarter-sized opening in the calvarium, where the button was removed, and extending two inches from it the evidence of a saber cut. He suffered slight difficulty in speech. (Fletcher.)

No. 839. Enormous Distension of Colon from Retained Feces.—This specimen was obtained by Drs. Gleb and Jones, Groton, S. D., from G. K., who went for one year and three days without a bowel movement. For the first six months he ate three hearty meals a day, doing harvest work. Later he could only do light work. At some points the bowels measured 19¼ inches.

Nos. 840-879. Collection of Vesical Calculi.—This fine series of stones was obtained by operations, during a residence of eleven years in Persia, by J. G. Wishard. Some of the cases were operated on under the most trying circumstances, in filthy and crowded quarters, and in some instances in stables.

No. 880. Ten Renal Calculi.—Product of one nephrectomy; weighing 5 ounces. The patient was a man, 39 years of age. Several years previously he had been injured by the caving in of a pit. Had hematuria for a week, but no further renal symptoms. For a year and a half previous to the operation by F. R. Charlton he had been treated for stomach trouble, persistent vomiting being the most conspicuous symptom. At the time of operation there was tenderness over the back and pus in the urine. Nephrotomy was first performed, a pint and a half of pus and the stones were removed; ten days later the kidney was removed. Recovery.

No. 881. Epidermal Cast of Foot.—Hemorrhagic smallpox. (Brayton.)

Nos. 882-902. Miscellaneous Specimens.—Including enteroliths, hair balls, foreign bodies removed from the larynx by operation, etc.

GEORGE E. SHAMBAUGH, CHICAGO (PRIVATE COLLECTION).

Nos. 903-906. Series of Wood's Metal Casts of Ear.—1. Two casts of labyrinth mounted on stiff cardboard, with drawings of anterior and posterior surfaces. 2. Metal cast of ear showing: (*a*) Meatus auditorius externus; (*b*) cellulæ mastoideæ; (*c*) meatus acousticus internus; (*d*) the osseus labyrinth. 3. Cast same as No. 2 and showing, in addition, the aquaductus vestibuli and the canaliculus cochleæ, with its accessory canal for the exit of the large vein from the cochlea.

Nos. 907-918. Series of Celloidin Casts of Labyrinth, mounted in cells and made from a preparation in which the blood vessels had been previously injected. 1. Complete cast of labyrinth, showing a perfect injection of the capillaries as well as the arteries and veins. Two drawings of the preparation in colors. 2. Cast of the cochlea, showing the arterial tree alone. Drawing of same in colors. 3. Drawings in colors to show following: (*a*) Basal coil of cochlea of embroyos 11 cm. long; (*b*) venous tree of cochlea; (*c*) basal coil of cochlea of fetus, full term; (*d*) cross section of cochlea; (*e*) detail of piece from basal coil of cochlea; (*f*) semicircular canal with ampulla; (*g*) detail drawing of section of the semicircular canal.

R. W. GILLMAN, DETROIT (PRIVATE COLLECTION).

Nos. 919-937. Series of Temporal Bones.—Arranged in order to show the varying distance of the lateral sinus from the spina sup. meatus. In No. 1 the distance was 21.0 mm. In each succeeding specimen the sinus was shown nearer the meatus, and in No. 17 they were only 6.0 mm. apart.

EDWARD EVANS, LA CROSSE, WIS. (PRIVATE COLLECTION).

Nos. 936-947. Products of Twelve Cholecystotomies.
Nos. 948-953. Appendiceal Specimens.

The stones in each cholecystotomy case were beautifully mounted on a board. The essential points of interest to the appendiceal specimens were the foreign bodies found in the appendix. In one case there was an apple seed; in another two live round worms were found in an abscess surrounding the perforated appendix.

The following exhibit was a beautiful series of casts of the bladder and prostate gland, designed to show the different types of hypertrophy of the latter, with the view of illustrating the particular form of surgical treatment indicated in each case.

BRANSFORD LEWIS, ST. LOUIS (PRIVATE COLLECTION).

No. 954. Bilateral Enlargement, with obstruction from pedunculated intravesical growth. Suprapubic operation advisable.
No. 955. Moderate Enlargement of Lateral Lobes; thick prostatic bar; deep bas fond; marked curvature of urethra. Favorable for perineal prostatectomy.
No. 956. Enlargement of Both Lateral Lobes; pedunculated median intravesical tumor from posterior commissure. Suitable for suprapubic removal.
No. 957. Pedunculated Median Intravesical Growth from posterior commissure. Favorable for suprapubic removal.
No. 958. Excessive Enlargement of Lateral and Median Lobes; direct pressure on both ureter openings producing dilatation of ureters and renal pelves. Favorable for combined suprapubic and perineal removal.
No. 959. Lateral Lobes, Enlarged; especially right; high prostatic bar, with small nodule on right; deep bas fond. Favorable for Bottini or perineal prostatectomy.
No. 960. Marked Enlargement of Both Lateral Lobes, and globular intravesical tumor from posterior commissure. Removal of tumor and both lobes required; best accomplished through perineal and possibly suprapubic combined routes. Bottini inappropriate.
No. 961. Moderate Enlargement of Lateral Lobes.—Pyramidal median projection capable of ball and socket effect. Suitable for suprapubic removal.
No. 962. Multiple Adenomata projecting into prostatic urethra. Favorable for perineal removal. Bottini inappropriate and inadequate.

HERMAN TUHOLSKE, ST. LOUIS (PRIVATE COLLECTION).

No. 963. Placenta Attached to Liver.

This remarkable specimen is the only one of its kind reported. The nearly full term fetus was removed from the abdomen by operation, but the woman died a few hours later from secondary hemorrhage.

H. F. HARRIS, ATLANTA (PRIVATE COLLECTION).

Nos. 964-966. Malarial Plasmodium.—Preparations stained by the modified Romanowsky process.
No. 967. Ameba from case of amebic dysentery in man.
No. 968. Ameba from a case of dysentery experimentally induced in a dog.

CLAUDE A. SMITH, ATLANTA, GA. (PRIVATE COLLECTION).

No. 969. Gross Specimens of Uncinaria americana.
Nos. 970-972. Microscopic Mounts, showing both the hookworm and ova.

MIHRAN K. KASSABIAN, PHILADELPHIA (PRIVATE COLLECTION).

Nos. 973-1012. Collection of Skiagraphs.

These skiagraphs were excellent. The more noteworthy among them were: (*a*) Pleurisy with effusion. (*b*) Vesical calculus. (*c*) Congenital dislocation of both hips (reduced by Lorenz).

W. C. FUCHS, CHICAGO (PRIVATE COLLECTION).

Nos. 1013-1113. Radiographs.—Rare in this collection were the following: (*a*) Four-month fetus differentiated from tumor; (*b*) pus sac-recurrent appendicitis; (*c*) floating kidney; (*d*) pericarditis; (*e*) gallstones; (*f*) cyst of the brain.

Medical Organization.

MEDICAL ORGANIZATION METHODS AND BENEFITS.

J. N. M'CORMACK.

(*Continued from page 623.*)

THE REMEDY.

Through the universal county society system it is proposed that there should be built up in each community, gradually and with the self-sacrificing labor incident to all important undertakings, a permanent organization, which will give artificially, as it were, the same opportunity for acquaintance, comradeship and improvement which comes naturally in those more favored vocations, of which the legal profession is a conspicuous example. To do this will require a union of all the forces at the command of the profession—its leaders, existing societies and schools. To secure this union, physicians must be convinced and students taught that no one was ever permanently benefited by traducing his competitors, or by the practice of any of the "black arts," and that the time has come for them to decide whether they will go on in the old, discredited courses, "learning nothing and forgetting nothing," as Macauley said of the Stuarts, wasting valuable time and bringing continued reproach on themselves and their guild, in endless, senseless, profitless bickerings, as in the past, or, instructed by what is going on around them in other callings, and in other sections in their own calling, get together for their own and the public good. There will be dissenters and pessimists, and the work may be difficult at the outset in many places, but each county accomplishing it and conducting its society in the broad, kind and mutually helpful spirit to be inculcated, will be an object lesson for its neighbors, good examples being just as infectious as bad ones. In such counties it will be an honor to be a physician, a pleasure to practice medicine, and the public will be benefited even more than the profession.

OTHER OBJECTS.

It must be borne in mind always that the organization and resulting pleasant relations indicated, important and essential as they are, are only means to far higher and more useful ends. Assuming that all this has been accomplished, or is well under way, the real work of the society should then be undertaken. To do this to the fullest advantage, study should be given to the many ways in which it may be made useful to the profession and people within its jurisdiction. Most of these are indicated in the by-laws briefly, but may require elaboration. In a measure, and in a very modest way at first, each society should be made a post-graduate school for the county. All who can do so should be urged to attend such schools in the medical centers from time to time for the purpose of getting out new editions of themselves, as it were, and to impart the information thus acquired, so far as possible, to their less fortunate colleagues who can not do so. Programs should include not only the usual papers and discussions, but also demonstrations, clinical cases, pathologic specimens, exhibits of the latest and best journals and books, and occasionally an address by some prominent invited guest. Younger members who can qualify themselves to do so should be encouraged to take up special research work. All of the proceedings should be so shaped and conducted as to encourage home study, both in the review of the elementary branches and as to the application of the latest and best methods in practice. A line of study after the plan of some of the university extension courses is greatly needed for the use of county societies and is likely to be developed soon. Public health questions should also have frequent place on the program. Aside from the prevention or restriction of epidemic and the ordinary communicable diseases, the complex problems incident to our rapidly-increasing population in this country, both rural and urban, must be met and worked out by the medical profession. Our rivers, which must be the source of water supply for future generations, are rapidly being converted into open sewers, poisoned, as are the soil and air, from ignorance more than greed on the part of municipalities, corporations and individuals. An educated public sentiment, which must originate and be directed by the medical profession, is needed, to demand and enforce preventive and remedial legislation in regard to these and other public dangers, unless we are to repeat the unfortunate experience of the older civilizations, whose people were repeatedly decimated and finally dwarfed as results of such neglect. The society should always be in touch with the county and municipal boards of health of its jurisdiction, and should lead in and co-operate with every proper effort to improve sanitary conditions. With these ends in view it should have a voice or be consulted in regard to new regulations and ordinances, and in the selection of the members of such boards.

MATERIAL AND BUSINESS INTERESTS.

Physicians are proverbially poor business men. As has been shown, this has resulted largely from the failure of even the best medical schools to give any instruction on the subject to start with, supplemented by an almost universal lack of organization, and false ideas as to a conflict of interest between local men. There has been a singular delicacy of sentiment, too, about the propriety of discussing this subject either in medical societies or before the public. All this must be changed. The time has come for everybody to understand that under modern conditions a physician who is a failure financially can not keep himself qualified and equipped for safe practice, and that in consequence low prices and rate-cutting are fruitful sources of danger to the public. Some voluntary understanding as to charges in each community is proper and necessary, but in order to prevent a possible abuse of the great power which a universal organization of the profession will give it is wisely written into the fundamental law of the entire system that no schedule of fees or agreement as to prices shall be adopted by any society. A medical trust would be objectionable and un-American as any other kind of trust. Beside, experience has shown that even the best-intentioned attempts to enforce such agreements by expulsion or other penalties have always resulted in further dissensions, with public sentiment and advantage on the side of the less scrupulous. Moral suasion, backed by an organized profession and an educated public sentiment, is the only remedy here as in all similar matters. For these reasons the by-laws also provide that "each county society shall set apart at least one meeting in each year for a discussion of the business interests of the profession of the county," and for efforts for a proper instruction of the public on the subject. At this meeting some leading members who have been most successful along just and ethical lines should open the discussion, which should be so directed as to indicate the best and most practical methods for the guidance of all. It should include the frequency and best methods of making collections; the expediency of a common collector for a number of physicians, on a salary and with a separate office, who can devote his entire time to their service; of the advantages of an office at the residence, or the economy of a joint office with different hours, or a common waiting room with individual consulting rooms, with the same office attendant and telephone; of a hospital owned or directed in whole or in part by the profession; of the advisability of taking advantage of modern pharmaceutic conveniences and dispensing their own drugs, and all similar questions, so far as they are adapted to the conditions and needs of that society.

In all of these matters the interests of the public should be fully and fairly considered, and at such meetings leading laymen might often be invited to take part in the discussions with profit to all. In fact, the mutual interests and obligations of the profession and public in everything should be iterated and reiterated as a means of education for both. The best and highest sources of information are now open and reasonably accessible to all medical men in this country, and every community is entitled to, and should have, competent physicians, and the best and most approved treatment in their afflictions. Most people who are in moderate circumstances, and all in emergency sickness, must receive this at the hands of their home physicians or not at all. Through systematic organization alone is it possible to furnish the incentives and opportunities requisite for such ends, and organization is incomplete until this has been done. This instruction, whether at home or in medical centers, with the incident equipment essential to its utilization in practice, is expensive and the public should be educated to its interest and duty in such a support of the profession as will enable its members to acquire them without depriving their families of the means of subsistence.

SOCIAL PROVISIONS.

The social features of the society should also receive careful attention, probably at the hands of a permanent committee with talent for such matters. Frequent and inexpensive lunches should be recognized as a legitimate and tasteful method of increasing the attendance and interest, and of promoting kind personal relations. In this respect the society should represent a gentlemen's club in its informal but dignified and respectful intercourse. It should be borne in mind by all concerned that members will take the time and trouble to attend only so long as the meetings are made pleasant and instructive. Little fear need be entertained on these points, however, if the councilors, and through them the profession at large, can once be made to understand the character, spirit and advantage of the work, so that each officer and member may be induced to do his full part.

QUALIFICATIONS OF COUNCILORS.

On account of the important powers and duties imposed on the council as a body, and still more on its individual members for several years to come at least, the office of councilor will be the most responsible within the gift of the state associations. Indeed, the inauguration and success of the entire work is so dependent on what he does that no one should accept the office who will not freely give the time and labor necessary to the efficient discharge of the duties. It is necessary that every one who would qualify himself for the office should make a special study of the constitution and by-laws which his state association has adopted, and of those which it has recommended for adoption by county societies. He should make himself familiar with the history of medicine, and especially with that of his own state and country. He should also inform himself as to the medical and health laws of the state. When possible, a joint meeting of the council and state board of medical examiners and the state board of health should be held early in the work in order that there may be that harmony of views and concert of action between those working for common ends essential to the best results. Representatives from the faculties of the various medical schools should be invited to such meetings for consultation as to the feasibility of establishing practical courses on ethics and business methods, as well as of having all advanced students advised as to the advantages of society membership and organization.

DUTIES OF COUNCILORS.

Possessed of the accurate knowledge and breadth of views which will qualify him for a discussion of the necessity, practicability and objects of the reorganization which the profession has undertaken, and being supplied with a card index register, or other reliable list containing the names of the physicians of each county in his district, the councilor is ready for active work. Selecting the county, a personal letter should be written to each physician notifying him of the place and hour agreed on for a meeting to consider the advisability of such an organization of the profession of his county as will improve all of its interests, scientific, social and material. The letter should be explicit, cordial in tone and should conclude by urging him to attend, and to notify and bring his professional neighbors and friends with him. A copy of the county constitution and by-laws should always be enclosed. Unless it is known that all of the physicians at the county seat are on unusually friendly terms the meeting should always be called at the courthouse, a hotel or other public place, and some conveniently located physician should be requested to arrange for the room and see that it is in order.

On his arrival the councilor will do well to call on each physician at the county seat, interest him in the meeting, and have him call up his friends out in the country, remind them of the meeting and urge them to come in. He is likely to meet with much discouragement and to hear many doleful complaints in this part of his work, but it may be encouraging for him to know that the best and most permanent results have often been secured in counties where conflicting interests and personal dissensions at first appeared so long established and irreconcilable that all were reluctant to attend. The importance of a full attendance at the first meeting, especially of those at the county seat, or those between whom dissensions or coolness exist, can hardly be overestimated. Such of these as fail to hear the address, to have an opportunity to take

part in the discussion which follows, and to come into fellowship then will usually prove much more difficult to deal with afterward.

(To be continued.)

Crawford County (Ind.) Medical Society.

This society has been organized with Dr. Frederick R. Gobbel, English, president; Dr. Charles D. Luckett, English, vice-president, and Dr. G. H. Abell, secretary and treasurer.

Durham County (N. C.) Medical Society.

Dr. Hubert A. Royster, Raleigh, councilor for the Fifth District, met with the physicians of the county at Durham, August 28, and organized a county medical society in affiliation with the state and National organizations, with an initial membership of 11. Dr. A. G. Carr, Durham, was elected president; Dr. Norman M. Johnson, Durham, vice-president, and Dr. George H. Ross, East Durham, secretary and treasurer.

McLennan County (Texas) Medical Society.

Physicians of McLennan County met at Waco, August 25, and organized a county medical society, adopting the constitution and by-laws recommended by the American Medical Association and electing the following officers: Dr. James C. J. King, Waco, president; Dr. Ralph E. Conger, China Spring, vice-president; Dr. Jesse J. Dean, Waco, secretary; Dr. J. D. Lovelace, Spegleville, treasurer, and Drs. Oliver I. Halbert, Garland B. Foscue and C. Enrique Smith, all of Waco, censors.

South Dakota Fourth District Medical Society.

A large number of physicians met at Huron, August 27, and organized this society, which comprises the counties of Beadle, Buffalo, Hyde, Hand, Hughes, Gerauld, Spink, Sanborn, Stanley and a part of Kingsbury. The following officers were elected: Dr. William H. Lane, Miller, president; Dr. Clark B. Alford, Huron, vice-president; Dr. Charles J. Lavery, Pierre, secretary; Dr. John L. Foxton, Huron, treasurer, and Drs. Lorme W. Robinson, Pierre, Isaac M. Burnside, Highmore, and E. A. Taylor, Huron, censors.

Jasper-Morton County (Texas) Medical Society.

Dr. Benjamin F. Calhoun, Beaumont, councilor for the Tenth (southeast) District, met with the physicians of Jasper and Morton counties at Jasper, August 30, and organized a medical society with the following officers: Dr. H. R. Hancock, president; Dr. Jefferson D. Yates, Kirbyville, vice-president; Dr. Thomas E. Stone, Jasper, secretary and treasurer; Drs. B. F. Yates, Jefferson D. Yates, Kirbyville, and G. T. Sutton, censors; Dr. Thomas E. Stone, Jasper, delegate to the state medical association, and Dr. Benjamin F. Bean, Kirbyville, alternate.

Green Lake County (Wis.) Medical Society.

The physicians of Green Lake County met at Dartford, August 20, organized a county medical society and adopted the constitution recommended by the American Medical Association for county societies. The following officers were elected: President, Dr. Charles E. Thayer, Markesan; vice-president, Dr. Arthur L. Travis, Princeton; secretary and treasurer, Dr. B. E. Scott, Berlin; delegate to state society, Dr. John S. Walbridge, Berlin, and censors, Drs. John S. Walbridge, Berlin, George E. Baldwin, Dartford, and Gertrude C. Crumb, Berlin.

Guilford County (N. C.) Medical Society.

On August 22 a meeting of physicians of the county was held in Greensboro to perfect reorganization in accordance with the constitution of the state society, at which the following officers were elected: Dr. Millard F. Fox, Guilford College, president; Drs. James A. Turner, High Point, and William J. Richardson, Greensboro, vice-presidents; Dr. Thomas R. Little, Greensboro, secretary and treasurer, and Drs. William J. Richardson, Thomas R. Little and Albert R. Wilson, all of Greensboro, committee on constitution and by-laws to report at the September meeting.

Orleans Parish (La.) Medical Society.

This society is in a flourishing condition, as evidenced by the large attendance at the meetings held in the heat of summer and by the very valuable papers contributed recently. The society now has 218 members, the largest number in its history. This gratifying state of affairs is to be attributed to the interest freshly awakened, in the first place, by the meeting of the American Medical Association held in New Orleans last May, and secondly, by the determination of the society to affiliate with the Louisville State Medical Society, as well as by the new regulations of the state society requiring each member to belong to his local society.

Societies.

COMING MEETINGS.

Medical Society of the Missouri Valley, Omaha, Sept. 14-15.
Medical Society of Virginia, Roanoke, Sept. 15-17.
Medical Society of the State of Pennsylvania, York, Sept. 22-24.
American Association of Obstetricians and Gynecologists, Chicago, Sept. 22-24.
Colorado State Medical Society, Denver, Oct. 6-8.
Medical Association of the District of Columbia, Washington, Oct. 6.
Idaho State Medical Society, Boise, Oct. 8-9.
Mississippi Valley Medical Association, Memphis, Tenn., Oct. 7-9.
Vermont State Medical Society, Bellows Falls, Oct. 15-16.
New York State Medical Association, New York City, Oct. 19-22.

Montana State Medical Association.—This association has filed its articles of incorporation, in accord with the resolution passed at the annual meeting in Butte, July 8, authorizing the special committee so to do.

Floyd County (Ga.) Medical Society.—At the first meeting after the organization of this society, held at Rome, August 25, Dr. Robert M. Harbin was elected president; Dr. Levi P. Hammond, vice-president, and Dr. William J. Shaw, secretary, all of Rome.

Boise (Idaho) Medical Association.—The organization of this association was completed, August 17, by the election of the following officers: Dr. George Collister, president; Dr. Warren D. Springer, vice-president; Dr. James L. Stewart, secretary and treasurer, and Drs. Lewis C. Bowers, Lewis, and Ed. E. Maxey, censors.

Pacific Coast Association of Railway Surgeons.—At a meeting in San Francisco, August 24, seventy-five railway surgeons organized this association, with the following officers: President, Dr. Walter B. Coffey, Southern Pacific, San Francisco; vice-presidents, Drs. Norman H. Morrison, Santa Fe, Los Angeles, Charles N. Ellinwood, San Francisco, and Kenneth A. McKenzie, Oregon Railway and Navigation Company, Portland; treasurer, Dr. Frank K. Ainsworth, Southern Pacific, San Francisco, and secretary, Dr. James P. Dunn, Southern Pacific, Oakland.

Cumberland Valley Medical Society.—At a meeting in Chambersburg, August 21, physicians of Washington County, Md., and of Cumberland, Adams and Franklin counties, Pa., met and appointed a committee consisting of Drs. John J. Coffman, Scotland; Robert W. Ramsay and P. Brough, Montgomery, Chambersburg; A. Barr Snively, Waynesboro; W. H. Brosius, Mont Alto, and David F. Unger, Mercersburg, to report on the feasibility of forming this society, at a meeting held in Mont Alto September 8.

BRITISH MEDICAL ASSOCIATION.

Seventy-first Annual Meeting, held at Swansea, Wales, July 28 to 31, 1903.

(By Our Special Representative.)

(Concluded from page 626.)

Leprosy: Its Etiology, Histology and Treatment.

MR. JONATHAN HUTCHINSON, London, advanced the following propositions:

That an overwhelming body of evidence is opposed to the belief that leprosy spreads by an ordinary mode of contagion (the breath, touch, clothes, bites of insects, wounds, etc.).

That hereditary transmission, if it ever occurs, is a rare event.

That commensal communication—that is, by eating food contaminated by a leper's hands—occurs occasionally, but is by no means frequent.

That in all countries where leprosy is not common a great majority of the cases are *de novo*, in the sense that there has been neither inheritance nor any exposure to risk of contagion.

That the facts as regard leprosy point to its being caused by some article of food.

That there is no other article of food which can be reasonably suspected excepting fish.

That the very excessive prevalence of leprosy in certain fishing districts is a fact strongly in favor of the fish hypothesis, and that its excessive incidence in Roman Catholic communities supports the same conclusion.

Various supposed objections to the fish hypothesis were answered, and it was urged that the amount of circumstantial evidence now accumulated is sufficient not only to justify but to demand that measures based on it should be adopted.

The Treatment of Advanced Tuberculous Disease of the Knee-Joint.

MR. G. A. WRIGHT and MR. W. F. HASLAM contributed a joint paper.

By advanced is implied the stage where operative intervention of some kind is imperative. The paper was based on an analysis of a large number of replies received from hospital surgeons to a series of questions sent to them by the authors. The points considered were:

1. The indications for operation in a case of tuberculous knee. 2. The nature of the operation selected. 3. If erasion is performed—(a) incision; (b) treatment of patella, crucial ligaments, and superficial and deep bone lesions. 4. If excision—(a) treatment of patella; (b) question of fixation of ends of bones. 5. Arrest of hemorrhage. 6. Drainage. 7. Dressings. 8. Splints. 9. Tendency to flexion after operation. 10. As to result in shortening in excision and erasion. 11. The influence of age in deciding as to which operation should be performed. 12. The seat of origin of the disease.

The Pathology of General Paralysis.

DR. W. FORD ROBERTSON opened the discussion on this subject. He supported the hypothesis recently enunciated by Drs. M'Rae and Jeffrey and himself, on the ground of bacteriologic and other evidence, that general paralysis is the result of chronic toxic infection from the respiratory and alimentary tracts, permitted by general and local impairment of the defenses against bacteria, and dependent on the excessive development of various bacterial forms, but especially on the abundant growth of a diphtheroid bacillus which gives the disease its special paralytic character. The widely-accepted view that general paralysis is dependent on a syphilitic toxemia will be controverted. It was maintained that syphilis only predisposes to the disease by impairing the general and local defensive mechanisms, and that it is merely one of many known agents that contribute to this weakening of the natural immunity. The possibility of the occurrence of a bacterial invasion of certain tissues as an essential part of the morbid process was also considered and some evidence bearing on the question brought forward.

Alcohol in Its Relation to Mental Diseases.

DR. THEO. R. HYSLOP said: The rôle of alcohol in the physical economy of the healthy body is more evil than good, and its use is abuse; in the unhealthy body its use may be compared to a loan—at heavy interest—to cope with immediate necessity, and to enable the bodily processes to recuperate.

In the degenerative processes due to chronic alcoholism the nuclear proliferation and overgrowth of the connective tissue cells appear to be closely related to the continued dilation of the vessels and the consequent increase of exudation of lymph to the tissues. In ordinary inflammation the exudate contains a relatively smaller quantity of proteids than does the blood plasma—owing possibly to the selective activity of the endothelial cells. In this case the extravasated leucocytes tend to undergo rapid destruction and dissolution.

When alcohol is conveyed to the plasma the metabolism of the leucocytes is retarded—owing to deprivation of the tissues of some oxygen; and there is retention and proliferation of the exuded material.

An explanation of the mnemonic defects and perversions due to alcohol is suggested; and it is contended that alcohol *per se* does not cause general paralysis.

The Pathology of Splenic Anemia.

DR. H. D. ROLLESTON, in discussing this subject, stated that the term splenic anemia is still often used in a vague sense to describe the clinical association of anemia with splenic enlargement not manifestly due to any definite cause. The relation between anemia and splenic enlargement is a wide subject, and it is therefore proposed to limit this discussion to chronic splenic anemia (primary splenomegaly of Brühl), recently described in greater clinical detail by Osler. The clinical characters of this condition are fairly definite, namely:

1. Splenic enlargement which can not be connected with any recognized cause.
2. Absence of any enlargement of the lymphatic glands.
3. Anemia of a type midway between secondary anemia and chlorosis.
4. Leucopenia, or at most no leucocytosis.
5. An extremely prolonged course lasting years; and
6. A tendency to hemorrhages, especially gastrointestinal, from time to time.

The main question for discussion is whether this clinical entity is a pathologic entity or whether it is merely a combination of symptoms which, under certain circumstances, may be due to a number of different conditions. No doubt some cases regarded clinically as chronic splenic anemia turn out after death to be due to syphilis, thrombosis of the portal vein, cirrhosis, etc., but in other cases there is no morbid lesion except a chronic change in the spleen, which may reasonably be explained as the effect of long-continued toxemic or infective processes. Further investigations—especially blood reactions—are required to show whether these two groups of cases can be separated clinically. Differential blood counts usually show a relative increase in the mononuclear and decrease in the polymorphonuclear leucocytes, but there is nothing pathognomonic. The spleen may show: (1) Increased fibrosis, with atrophy of the malpighian bodies either alone, or (2) in addition to varying degrees of endothelial proliferation; when the latter is very extreme it has been described as a primary malignant growth (Gaucher, Ramond and Picou). Are these appearances different stages in the same process, or are they manifestations of different causes? and to what extent are they pathognomonic of splenic anemia? In some cases hepatic cirrhosis supervenes as a terminal stage (Banti's disease), in other cases slight and latent fibrosis of old date is found in the liver. Is the splenomegaly due to processes originating in the intestinal tract, and so an allied condition to cirrhosis of the liver? Bacteriologic examination of the spleen has not yet given any help. Further knowledge as to the state of the bone marrow, and of the factors inhibiting its hemopoietic activity in splenic anemia, is wanted. In conclusion, although chronic splenic anemia may be regarded as a clinical entity its causation is unknown, and at present, therefore, there is not sufficient evidence to consider it a definite pathologic entity.

Treatment of Convergent Squint.

MR. GUSTAVUS HARTRIDGE said the treatment of convergent concomitant strabismus in a scientific manner can only be approached by the consideration of the various factors which help to produce the disorder, and by a careful examination of every case, so that the value and importance of each factor may be ascertained.

Concomitant convergent strabismus is a condition affecting both eyes—it is a binocular defect, and is the result of excessive innervation of the internal recti muscles excited by the associated act of accommodation. The factors which may assist in the production of squint are:

1. Hypermetropia.
2. Imperfect development of the fusion faculty.
3. Defective visual acuity in one eye.

4. The anatomic position of rest of the eyes.

These various factors do not play the same part in every case; they may not all be present, hence a careful and systematic examination of each case is essential. The objects to be obtained by treatment are:

1. The correction of the deformity.
2. Establishment of binocular vision for all distance.

The treatment may be divided into: Optical, orthoptic, operative.

The importance of an exact optical correction is beyond all question, and in many cases results in a complete cure. Orthoptic exercises are of great value in many cases, but must be commenced early. They consist of:

1. Covering up the fixing eye for a certain time daily.
2. Practice with a stereoscope.
3. Bar reading.

The optical and orthoptic treatment must be faithfully carried out for twelve months before any operative treatment can be entertained. When an operation has been decided on we have to decide: What operation shall be undertaken? We have at our disposal four operations:

1. Simple tenotomy of one or both eyes.
2. Simple advancement.
3. Tenotomy with advance of the opponent muscle.
4. Stretching of one of the muscles.

The chief points on which he invited discussion were:

1. When is an operation necessary or justifiable?
2. What operation gives the best results?

Operations on the Temporal Bone for Otitis Media Purulenta.

DR. ARTHUR HARTMANN, Berlin, spoke on this subject.

1. *Acute Inflammation.*—As a rule, in opening the mastoid in acute inflammation the antrum should be opened in order to have free communication with the tympanic cavity.

Only in cases of abscess in the mastoid, if the internal wall of the abscess seems to be healthy and if there is no swelling in the meatus and on the upper part of the membrane, we need not open the antrum.

In order to effect a rapid and lasting cure the entrance to the cavity must be made very wide. All the bone over the diseased part and the external part of the posterior wall of the meatus must be removed. After this the soft integuments fill the cavity.

2. *Chronic Inflammation.*—The operation on the temporal bone in chronic purulent inflammation of the middle ear when it can not be cured by other treatment, including that by the tympanic tube and by excision of the ossicles, consists in the radical operation.

The radical operation must be so performed that all affected parts of the cavities are rendered accessible and visible.

For this purpose:

1. All the bone outwards of the affected parts must be removed.
2. The external meatus must be much enlarged.

This enlargement can be effected:

(a) If the destructions are not very great by means of Korner's flap.

(b) In cases of large destructions, as in cholesteatoma, by the Y cut of Siebenmann, combined with the excision of a part of the cartilage of the choncha.

For cases of labyrinthine suppuration the labyrinth can be opened without injuring the facial nerve either from the semicircular canals or from the promontorium according to the seat of the disease.

The Pathology and Treatment of Chorea.

In descanting on this subject Dr. D. B. Lees spoke of the chorea of childhood alone. He said chorea is not merely a disorder of muscular movement. There is clinical evidence of an abnormal state of the rolandic cortex, as also of other parts of the brain. He alluded to the implication of speech, of memory, and of the mental and moral faculties. The morbid state sometimes in chorea is intense, often very chronic, yet not destructive, and usually ends in complete recovery. This suggests that the cause is probably a toxemia.

He described the pathologic and histologic results in fatal cases. There is clinical evidence of a morbid blood state in chorea. Any of the manifestations of rheumatism may accompany it. Strength of the evidence of the connection between the two can only be appreciated by keeping all these manifestations in mind. Chorea is often the first rheumatic symptom. Bacteriologic evidence is as yet scanty, but suggestive.

He concludes that chorea is, in the great majority of cases, essentially a rheumatic symptom. Other causes are possible, but rheumatism should be suspected in every case.

Antirheumatic treatment, if sufficiently vigorous, produces very satisfactory improvement in acute chorea. Large and frequent doses of salicylate are required. Other measures should be employed. Insufficient doses are usually given because of the tradition that salicylate is a cardiac depressant. This action is really due to acute rheumatic dilation of the heart, and not to the remedy. The chronic cases are naturally less influenced by the drug because motor centers may remain abnormally excitable after the action of micro-organisms has ceased, yet here also the salicylate is of service, if used freely. Other remedies should be used, such as arsenic, antipyrin, ergot, etc.

The Upper Respiratory Tract as a Source of Systemic Infection.

DR. DEHAVILLAND HALL brings forward cases to show that typhoid fever may start in the larynx. He points to the initiatory symptoms of measles, influenza and whooping cough as clearly indicating that the virus of these diseases enters the system through the upper respiratory tract. Diphtheria is essentially a local disease at its commencement, and the specific bacilli may enter at the nose, nasopharynx, pharynx (the usual situation) or larynx; the secondary symptoms are due to the absorption of toxic materials secreted by the bacilli during their growth. Cases are brought forward to show that the virus of scarlet fever may enter the system through a wound of the nasal mucous membrane. He is of opinion that there is much to be said in favor of the view that tonsillitis is a primary infective disease of the lacunæ, and that rheumatic fever is a secondary disease arising from the absorption of microbes or their products into the system. He emphasizes the importance of the careful treatment of even slight tonsillar affections in view of the danger of systemic infection. Septicemia, pyemia and erysipelas are shown to be diseases which certainly enter the system in many cases through the upper respiratory tract. Occurrence of primary tuberculosis of the nose, pharynx and larynx, and the recognition of latent tuberculosis of the tonsils, both faucial and pharyngeal, point to the possibility of the tubercle bacillus entering the system via the upper respiratory tract. Cases of syphilitic infection through primary sores in nose, nasopharynx, pharynx and larynx are mentioned.

DR. JOBSON HORNE, in a paper on the same subject, deals mainly with three points: 1. That the upper respiratory tract is more frequently than is generally stated a site of primary infection with systemic diseases other than those commonly assigned to it, and that a more routine examination of the region should be made in the clinical investigation of diseases of obscure origin. 2. That the region is not only a source of, but is also a factor in, modifying or arresting infection. Lastly the surgical treatment of such diseases is considered with reference to the foregoing.

By way of illustrating these points the following diseases are more especially discussed: Infective endocarditis, tuberculosis, lymphadenoma and lymphosarcoma.

As to infective endocarditis, evidence is adduced to show that the primary infection at times is in the larynx.

In regard to tuberculosis, the relative virulence of moist and dry infection is considered. The part played by the upper respiratory tract in tuberculosis is regarded as three-fold: (a) Direct inoculation—e. g., primary tuberculosis of nose, fauces, postnasal space, soft palate, pharynx, partoid gland, tongue, larynx. (b) Indirect infection, the lymphoid tissue

acting as a channel to convey infection—e. g., primary tuberculosis of the ear, of the cervical lymphatic glands, descending infection of lungs via cervical lymphatic system. (c) Bactericidal action, the lymphoid tissue modifying or preventing infection.

As to lymphadenoma, the relationship of the disease to tuberculosis is considered, and positive evidence is adduced to prove that the disease may be regarded as parasitic, and that infection at times occurs through the upper respiratory tract. Cases in which this evidence is complete were cited.

Relative to lymphosarcoma, pathologic evidence is offered in favor of the thoracic disease, histologically described as "lymphosarcoma," being due to infection through ulceration of the larynx.

The surgical treatment of tuberculosis of the larynx and lymphadenoma was considered with reference to the foregoing remarks.

Officers.

The president-elect of the association is William Collier, M.A., M.D., F.R.C.P., Oxford, and Oxford, England, was selected as the place for holding the next annual meeting.

CANADIAN MEDICAL ASSOCIATION.

Thirty-sixth Annual Meeting, held at London, Ont., Aug. 25 to 28, 1903.

(*Concluded from page 627.*)

President's Address.

Dr. W. H. Moorehouse, London, Ont., delivered the president's address on the evening of the first day. He urged the need of a uniform standard of medical education throughout the dominion, and he thought that this would be brought about as soon as the political horizon became cleared.

THE PATENT MEDICINE EVIL.

President Moorehouse spoke in vigorous terms of the patent medicine craze. The evils were many and readily understood. Certainly not the least was the alcohol habit, which, under the insidious insinuating form of a harmless medicine, was stalking in our midst like a midnight pestilence. Continuing, he said:

> Can not something be done to shield the public from this great evil? Shall we, the members of this enlightened profession, who see this monster, with its many-sided evils, having its bold, indecent advertisements in the press, pervading even the religious journals, clothing these nostrums with an air of respectability; we, who daily meet in our rounds melancholy examples of this terrible delusion, I say, shall we not raise our voices in loud protest against it?

Resolutions.

Resolutions were adopted, one asking the British Medical Association to meet in Toronto in 1905, another pledging the endeavors of the members to bring about a system of municipal sanatoria for the treatment of tuberculosis.

The Cardiac Complications of Influenza.

Dr. E. G. Wood, Nashville, Tenn., said that only a want of recognition of the cardiac dangers can account for the common practice of administering such large and frequently repeated doses of the coal-tar drugs in influenza. Months after an attack of la grippe a man still complains of unusual weakness; he is short-winded and sweats on slight exertion. Physical examination may be negative, yet he is suffering from cardiac weakness due either to functional or muscular disease of the organ.

The cardiac complications may be divided into organic and functional.

ORGANIC.

1. *Pericarditis* is either primary, when it complicates influenza without other organs being affected, or secondary, where it occurs in association with pneumonia or pleurisy, the latter being more frequent..

In grippal pericarditis purulent effusion is comparatively frequent and myocarditis is commonly associated with it. Pericarditis may be present without symptoms.

2. *Endocarditis.*—This occurs more frequently than usually supposed. It is rarely primary, and in the great majority of cases it is secondary to pneumonia. The infective agents are the pneumococcus, streptococcus, staphylococcus and the bacillus of Pfeiffer. Endocarditis may be (1) simple, (2) ulcerative. The simple may present the usual symptoms or may be unrecognized. Ulcerative endocarditis may occur during the attack, but appears more frequently in the convalescing period.

3. *Myocardial Changes.*—The bacillus of influenza elaborates a poison which causes degenerative changes in the myocardium, and when convalescence begins and the patient gets up the heart muscle is unable, under the increased strain, to perform its functions, and palpitation, dyspnea, weakness and collapse are complained of. These symptoms call for a careful examination. A small, feeble pulse, unusually slow or rapid, with a short, feeble first sound, a weakening of the second sound, and a weak cardiac impulse, with increased deep dulness make us think of myocarditis with dilatation.

FUNCTIONAL DISTURBANCES.

The symptoms are attributed to the action of the influenzal poison on the cardiac nervous mechanism; either on the vagus or the cardiac ganglia. The principal functional cardiac disturbances are: 1, palpitation, which is very common; 2, irregular action of the heart; it may occur during or after the attack; 3, bradycardia, which is the most dangerous, as it sometimes leads to fatal syncope; 4, tachycardia; this is more common than bradycardia. These functional disturbances are often difficult to diagnosticate from the organic affections; they usually disappear in a few weeks.

As a rule, in addition to significant subjective symptoms, physical examination will show a feeble, diffuse cardiac impulse with a weak first sound, and in many cases an increased area of dulness. The strength and character impulse and sounds are much more important than the presence of a murmur or irregular rhythm.

In conclusion the author depreciated the use of coal-tar products, especially in patients past middle life.

DISCUSSION.

Dr. Samson, Windsor, in the discussion spoke strongly against the use of the coal-tar products in influenza.

Dr. McPhedran, Toronto, said that in certain cases he thought they were allowable, and that the number of cardiac cases found in influenza was relatively small. He had seen no organic ones.

Dr. H. A. McCallum, London, thought that strychnia and digitalis should be used.

The Relation Between the General Practitioner and the Specialist in Regard to the Treatment of Intranasal Disease.

Dr. J. Price Brown, Toronto, Ont., said that if the required treatment can be done by the family physician by all means let him do it, but if not he should refer the case to the specialist. Every practitioner should be able to examine the nose with the rhinoscope both anteriorly and posteriorly, to discriminate between the normal and abnormal and to diagnose the principal forms of disease which may be found within the organ.

Many conditions he can treat successfully. The instruments he may require are neither very numerous or costly. They consist of head mirror, throat mirrors of different sizes, nasal spiculæ of different widths, curved or angular scissors, cotton applicators, tongue depressor, saws, snares, insufflators and atomizers.

There are certain conditions which simple treatment will relieve, but in which persistent and regular treatment is imperative; particularly atrophic rhinitis. In many cases of subacute and chronic catarrh, the general practitioner can do all that is required. The author outlined the treatment of these affections.

Other papers read were by Dr. H. Meek, London, Ont., on Alexander's operation; Dr. P. G. Goldsmith, on "Causes and Treatment of Postnasal Discharge." Cases of various conditions were reported by Drs. Hadley Williams; J. Alex. Hutchinson; John Wishart; R. Ferguson, London, Ont.; H. Howitt, Guelph, Ont.; Hodge, London, Ont.; and R. B. Robinson, Ottawa. Drs. Geo. M. Gould, Philadelphia, and E. J. Barrick, Toronto, also read papers.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Night-sweats.

The following combination is recommended by *Le Mois Therapeutique* in the treatment of night-sweats due to tuberculosis:

℞.	Balsami peruvianæ	m. xv	1
	Acidi formici		
	Chloralis hydratis, āā	gr. lxxx	5
	Alcoholis (pure)	ʒiiiss	100

M. Sig.: Sponge the body with the foregoing combination at bedtime.

The following combination is frequently used locally in the treatment of night-sweats:

℞.	Alumeni	ʒiv	15
	Alcoholis	ʒii	8
	Aquæ	Oi	480

M. Sig.: Apply locally night and morning with a sponge.

Sunburn and Prickly Heat.

The following combinations are recommended by *Merck's Archives* in the treatment of sunburn:

℞.	Sulphuris precip.	ʒi	30
	Zinci oxidi	ʒiv	15
	Olei amygdalæ (expressed)	ʒi	30
	Lanolini	ʒi	30
	Ext. violet	ʒi	4

M. Sig.: Apply freely two or three times daily; or:

℞.	Ichthyol	ʒii	8
	Olei amygdalæ (expressed)	ʒii	8
	Ung. aquæ rosæ	ʒvi	25
	Lanolini	ʒvi	25
	Olei rosæ	gtt. ii	12

M. Sig.: Apply two or three times daily; or:

℞.	Olei olivæ	ʒiv	15
	Menthol	gr. xv	1
	Ung. aquæ rosæ		
	Lanolini, āā	ʒvi	25

M. Sig.: To be used as a dusting powder several times daily.

In cases of prickly heat the following is also recommended:

℞.	Calamini	ʒiv	15
	Zinci oxidi	ʒii	8
	Ichthyol	ʒi	4
	Glycerini	ʒii	8
	Aq. laurocerasi q. s. ad	ʒvi	180

M. Sig.: Shake well and apply several times daily; or:

℞.	Pulv. amyli	ʒiv	15
	Lycopodii	ʒii	8
	Zinci oxidi	ʒi	4
	Ichthyol	ʒi	4

M. Sig: To be used as a dusting powder several times daily. Alkaline, borax or bran baths at the body temperature are also beneficial. Anointing the body night and morning with some fat, such as petrolatum or cacao butter is of service as a prophylactic measure in persons who are subject to this annoyance. Silk or fine woolen underclothing should be preferred to cotton or linen. Strict attention to the elimination by the bowels and kidneys and a carefully-selected and nutritious diet are of great importance. As a drink, lemon juice or lime juice in barley water is very cooling and relieves the thirst.

Glycoheroin for Cough.

According to Haas and Saxe in *Amer. Med.* the most satisfactory method of prescribing heroin is in the form of the glycerin solution, glycoheroin. They used it in 20 cases of cough and 12 were cured, 7 improved and 2 unimproved. Their conclusions are that this is the best form in which to use heroin; it is especially valuable in whooping cough, as small doses of it are well borne by children and even infants, and the results very prompt and permanent. It is of service in pulmonary tuberculosis, in reducing the cough, nightsweats, pain and temperature without disturbing the appetite and digestion. In acute and chronic bronchitis the most obstinate cases yielded to it.

Mucomembranous Enteritis.

The most frequent cause of mucomembranous enteritis, according to A. Robin in *Amer. Med.*, is gastric hyperacidity. Consequently to correct the cause the following should be given:

℞.	Precip. calcii carb.		
	Magnesiæ (calcined), āā	ʒiss	6
	Sodii bicarb.	ʒi	4

M. Ft. chartulæ No. xii. Sig.: One powder after each meal, in the middle of the afternoon, and at bedtime in a little water.

Careful attention should be given to the diet. Fats, sauces, raw or fried articles, condiments and acid substances should be avoided. He recommends intestinal irrigation to be repeated daily for eight days, then two or three times a week. One quart of water should be used at a time at a temperature of 95 F., to which five or six drops of the tincture of sage (salvia) have been added in order to favor the contractility of the intestine.

Feeble laxatives should be employed; one or two teaspoonfuls of castor oil may be given, to which two or three drops of the following have been added:

℞.	Tinct. opii		
	Tinct. belladonnæ		
	Tinct. hyoscyami, āā	ʒiss	6

M. Sig.: Three drops added to one or two teaspoonfuls of castor oil and taken as directed.

He also recommends massage daily, following the course of the large intestine.

Epicarin in Tinea Tonsurans and Circinata.

Van Harlingen and Dillard, in *Amer. Jour. Med. Sciences*, report excellent results from the employment of epicarin in the treatment of tinea tonsurans and tinea circinata. It was also used in the treatment of scabies, but with less satisfactory results.

It was used combined as follows:

℞.	Epicarin	ʒiss	6
	Alcoholis	ʒii	60

M. Ft. lotio. Sig.: Apply locally.

Or in the form of an ointment, as follows:

℞.	Epicarin	gr. c	7
	Cretæ albæ	gr. xxx	2
	Vaselini albæ		
	Lanolini, āā	ʒiss	45

M. Ft. unguentum. Sig.: Apply locally.

Each of the foregoing combinations proved very efficient in the treatment of tinea. However, the results obtained in scabies were not satisfactory, as the ointment irritated the skin quite severely and gave but little relief to the pruritus, which yielded promptly to the naphthol and sulphur ointment.

This preparation, according to the authors, is a condensation product of creasotinic acid and beta-naphthol, therefore combining the properties of creasote and naphthol. It is a reddish amorphous powder, soluble in alcohol, ether and liquid vaselin.

Chloroform as a Teniafuge.

Chloroform is a very efficacious teniafuge according to M. Leger as noted in *Merck's Archives*. In prescribing it for this purpose he recommends that the patient be kept on a milk diet for twenty-four hours previous to its administration, and a purgative enema given.

The next morning the following mixture is administered:

℞.	Spts. chloroformi	m. xl	2 65
	Syrupi	ʒvi	25
	Aquæ	ʒiv	120

M. Sig.: To be given an ounce at a time at intervals of forty-five minutes.

Between the third and fourth doses one ounce of castor oil is given or an ounce of German brandy. Very satisfactory results were obtained by him by this method of treatment, as shown by statistics given.

Local Hyperidrosis.

In the treatment of hyperidrosis of the hands, feet or axillæ, according to an abstract in the *N. Y. and Phila. Med. Jour.*, local baths of vinegar may be used, an infusion of walnut leaves and alum, a solution of potassium permanganate, or a tablespoonful of commercial formol in a quart of water. Subsequently the affected areas should be rubbed with the following lotion:

℞.	Naphthol	℥i	4
	Glycerini	℥ii	8
	Alcoholis	℥xx	80

M. Ft. lotio. Sig.: Dilute one half with water and apply locally; or:

℞.	Thymol	gr. xv	1
	Acidi tannici	gr. lxxv	5
	Spts. vini gallici (camphorated)	℥vii	210

M. Ft. lotio. Sig.: Apply locally.

The affected parts should then be dried well and powdered with talcum, starch or bismuth subnitrate, or with the following combination:

℞.	Acidi salicylici	gr. xlv	3
	Amyli	℥iiss	10
	Pulv. talci	℥iiss	75

M. Sig.: Locally applied; or:

℞.	Acidi salicylici	gr. xlv	3
	Pulv. alumeni Naphthol B., āā	gr. lxxv	5
	Sodii boratis Pulv. amyli, āā	℥iiss	10
	Pulv. talci	℥iiss	75

M. Ft. pulvis. Sig.: To be dusted in the shoes in cases of sweating of the feet.

The following combination is said to serve a good purpose in excessive hyperidrosis:

℞.	Bismuthi subnitratis	℥iv	15
	Sodii salicylatis	gr. lxxv	5

M. Sig.: For external use as a dusting powder in the shoes.

The following should be rubbed between the toes once a week:

℞.	Plumbi oxidi rubri	gr. xv	1
	Liq. plumbi subacetatis	℥i	30

M. Ft. lotio. Sig.: Apply once a week between the toes in excessive perspiration of the feet.

Medicolegal.

Use of Morphin Not "Cruel Treatment" of Spouse.—The Supreme Court of Georgia holds, in the case of Ring vs. Ring, that the habitual and intemperate use of morphin, unaccompanied by any willful infliction of pain, bodily or mental, on the complaining party, such as reasonably justifies an apprehension of danger to life, limb or health, is not such cruel treatment as the law recognizes as a ground for divorce.

Duty of Injured Person in Employment of Physician.—The Appellate Court of Illinois for the Fourth District holds, in Chicago & Eastern Illinois Railroad Company vs. Burridge, a personal injury case brought by the latter party, that an instruction stated the law correctly which told the jury that it was the duty of the party suing "to employ such doctor or doctors for the treatment of his injuries as ordinary prudence in his situation at the time of the injury and thereafter required; and to use ordinary judgment and care in doing so, and to select only such doctor as was of at least ordinary skill and care in his profession; but the law does not make him an insurer in such case that the doctor will be guilty of no negligence, error in judgment or want of care, and where such errors or mistakes occur in the treatment (the injured party using ordinary care) the injury resulting from such mistakes is properly regarded as part of the immediate and direct damages resulting from the original injury."

Liability for Support of Quarantined Persons.—The Supreme Court of Nebraska holds, in Dodge County vs. Diers, that, in the absence of a statute, a county is not liable for necessaries furnished to persons not paupers while quarantined in their residence for the time being. The Supreme Court Commissioners say that some states have statutes by virtue of which such liability exists in certain cases. But the liability in these cases is recognized as completely statutory so that if the quarantine was not imposed by the authority named in the statute, or was imposed before the statute took effect, or the persons quarantined did not come within the purview of the provisions creating liability for necessaries, the county or municipality has never been held. In consequence, where the statute goes no further than to provide for the maintenance of indigent persons while quarantined, or provides that the county or municipality shall be liable in case those chargeable with their support are unable to maintain them, the burden is on the claimant to show that the patients were paupers, or that those primarily liable were unable to respond. The mere fact that they are quarantined for the public safety does not relieve persons who are able to support themselves of the duty of so doing.

Larceny of Antitoxin.—The Supreme Court of New York, Special Term, New York County, says, in the case of People, on the relation of Lacina vs. Lavin, that the City of New York, through its department of health, for several years has been, and still is, distributing free of charge to the poor people antitoxin to be used as a preventive against and cure for diphtheria. The department of health consigns the antitoxin, which is put up in small phials, to certain druggists in the city, and authorizes them, on the presentation of a certificate by any physician of the city, to deliver to the physician free of charge, for the use of a poor patient, one or more phials of the antitoxin, the certificate stating that this antitoxin is for the treatment of a poor patient, to whom payment for the same would be a hardship. The relator, a practicing physician, who obtained three phials of the antitoxin on one of these certificates, the court says, was the agent of the city to administer the antitoxin to the patient he obained it for if she was unable to pay for it, and only in that event; but he administered it to her knowing that she was able to pay for it, and therefore he deviated from the terms of his agency, and did so to his own pecuniary advantage. In other words, he appropriated the antitoxin to his own use, and rendered himself amenable to subdivision 2 of section 528 of the Penal Code of the State of New York, which declares it to be larceny for one to appropriate to his own use public property in his control.

Employment of Nurse by Health Officer's Substitute.—The Appellate Court of Indiana, Division No. 1, says, in the case of Monroe vs. City of Bluffton, that the secretary of the board of health for the city and county, having given written authority to another duly qualified, practicing physician to act as health officer during his absence, thereafter absented himself from the city and county, and never afterward acted or assumed to act as health officer. The Indiana statutes provide that, "In case of death or removal of any town, city, or county health officer, the vacancy thereby created shall be immediately filled by the president of the board of trustees of the town, or the mayor of the city, or the county auditor as the case may be," etc. But from the time of the above appointment or attempted substitution, and for 40 days continuously thereafter, neither the county nor city had any health officer other than this appointee or substitute. In the meantime, the latter, acting under this appointment, and also verbal directions of the secretary of the State Board of Health directing him to immediately quarantine the house of the party suing, quarantined the house, and ordered and contracted with the party suing to take charge of and nurse and care for an indigent smallpox patient who had come there. The party suing believed at the time that the one so employing her was the health officer of the city, and the city subsequently paid the guards he contracted with for guarding the house. The court holds that the complaint of the party suing, setting forth substantially these facts, stated a cause of action for the value of the services rendered as nurse. It says that the Indiana statutes not only give local boards of health authority to take the necessary action to prevent the spread of contagious and

infectious diseases, but they make it their duty to do so in all cases, and that they shall take prompt action in such matters. No more important duty rests on the state than the preservation of the public health, and, to secure and protect the public health against the very dangerous and contagious disease of smallpox, the local instrumentalities and agencies created by the state are required to act promptly and effectively. It is true the secretary of the board of health does not have absolute authority independently of the board in matters pertaining to the public health. But, even if it be conceded that under a strict and literal interpretation of the law the party suing could not recover, courts are not always required to give full force to the exact letter of the law, but are oftentimes permitted, nay more, required, to relax somewhat the rigor of an exact compliance. It is true the general rule is well established that a person dealing with the agent of a municipality must take notice of the limit of his powers, and must know whether the authority assumed is within the statute. But it must be conceded that the facts pleaded showed an emergency existed requiring immediate action. And it may rightfully be said that the employment of a nurse to care for a person suffering from smallpox in a malignant form was an essential precautionary measure to prevent the spread of the disease, and that all that the health officer's substitute did was one entire transaction, which the city must repudiate or ratify as a whole. The city was without a regularly appointed health officer who could act when the emergency arose. The public at large, and especially the inhabitants of the city, were vitally interested in having precautionary measures against the spread of the disease taken immediately. The party suing and her premises were properly quarantined, and by one assuming to have authority to act. He did nothing that the city itself might not have done, but did only what the city in the proper exercise of its duty under the circumstances was required to do. The court thinks that when all the facts and circumstances are taken into consideration, the emergency that existed, the purpose for which the services were performed, the object sought to be accomplished, the necessity that existed that the services be performed, the law implied a promise to pay the reasonable value of the services of the party suing.

August 29.

1 *The Treatment of Wounds Inflicted with the Toy Pistol. W. Scott Schley.
2 *Is There a Constant Pigment Cell in the Cochlea? George S. Dixon.
3 An Improvement in Radiography. A Print Made by Direct Exposure and Developed in Half a Minute without a Dark Room. Sinclair Tousey.
4 *Regicides; Sane and Insane. (Continued.) E. C. Spitzka.
5 *Personal Experience Regarding Anesthetics. Edward W. Lee.
6 *Primary Tuberculosis of Abdominal Lymph Glands in the Adult. Paul F. Morf.
7 General Remarks on Diseases of the Stomach. Harry Warren Lincoln.
8 Report of Case of Pistol Shot Wound in the Neck; Laminectomy; Results. John C. Murphy.
9 The Treatment of the Summer Dairrhea of Children. (Concluded.) Adrian A. Landry.

1. **Toy Pistol Wounds.**—Schley insists on the importance of thorough cleansing of the wound, using an additional free incision, curetting away the sloughing areas, with free irrigation with saturated solution of boric acid or 1/5,000 bichlorid. The edges of the wound of entrance are trimmed, and a comparatively loose, moist, iodoform gauze packing with a large wet dressing of 1 to 5,000 or 6,000 bichlorid is applied and kept wet at home. Absolute thoroughness in this way has given excellent results. The danger and futility of attempting to care for these cases by a small incision or simple curetting and washing of the wound and removal of the wad, if it happens to be superficial, is proven by his past experience. Through-and-through drainage has been used where the hand has been nearly perforated, but the free opening of one side only is almost always sufficient. None of the cases thus treated have developed tetanus and tetanus antitoxin has been given but four times. He remarks that there are generally two wads to be looked for, and that the great danger of these wounds is the carrying in of extraneous matter.

2. **Cochlea Pigment Cells.**—In the case reported by Dixon there were found large numbers of brown, iron-free, pigmented cells like the branched cells of the choroid and iris. He thinks that these are probably normal and constant in the human cochlea and may become more abundant under certain circumstances, as in the case reported.

4. **Regicides.**—Spitzka continues his argument in respect to the non-insanity and degeneracy of regicides.

5. **Anesthetics.**—Lee is not enthusiastic over spinal cocainization. He finds local anesthesia with cocain often effective, and has done several abdominal sections by it. He has used the infiltration method in hernia and appendicitis. His most satisfactory work, however, has been done on the extremities. He finds if the limb can be elevated until quite blanched and an Esmarch bandage applied, local anesthesia is much more effective, and is free from the disadvantages which often follow when cocain is permitted to enter the general circulation. In one or two minor operations he has been able to use hypnotism, and reports one case. As regards general anesthesia, his preference is decidedly for chloroform. He thinks that ether has many disadvantages and more generally requires an expert for its administration than does chloroform. He does not consider it safer. He has even had chloroform administered by a layman in his practice, though he kept close watch of its action, and says he would have been afraid to use ether under such circumstances. In conclusion he remarks that there is no agent that will obliterate pain in surgical operations that is without danger.

6. **Tuberculosis of the Abdominal Lymph Glands in the Adult.**—This subject has received little attention. Morf investigated the postmortem records of the Rush Medical College and found 9 cases with involvement of the abdominal lymph glands out of 86 tuberculous cases. He reviews what has been written on the subject and the symptoms. The pain is not usually acute nor superficial. It is not attended with distension of the belly, vomiting, dulness nor diarrhea. It may, however, cause acute symptoms without ulceration of the peritoneum, as shown by a case reported by Richardson. The presence of a nodular, abdominal tumor in connection with localized pain and without diarrhea and extending over a long duration is significant. The usual general treatment is advised. Surgical intervention may be considered and abdominal section should be recommended in tubercular mesenteric disease, so soon as the abdominal symptoms make the diagnosis reasonably certain, as he thinks it probable that the same effects would follow as in tubercular peritonitis. The article concludes with a bibliography.

Boston Medical and Surgical Journal.

August 27.

10 *The Invalid's Egypt. F. Gordon Morrill.
11 *The Treatment of Degenerative Diseases of the Nervous System by Massive Doses of Strychnia, with Special Reference to Tabes Dorsalis, Progressive Muscular Atrophy, Optic Nerve Atrophy and Pseudomuscular Hypertrophy. Graeme M. Hammond.
12 *A Brief Summary of the Surgery of the Esophagus. Samuel J. Mixter.
13 Inferences to Be Drawn from the Examination of the Gastric Contents. Elliott P. Joslin.

10. **The Invalid's Egypt.**—Morrill describes the climate in the various health resorts of Egypt, of which he thinks Assouan has probably the best advantages. Its climate is warmer and dryer than most of the others, and it is easily accessible by train or boat. He warns against the incautious use of drinks in the form of water and milk without sterilization, and the avoidance of "catching cold," which is very easily accomplished in Egypt, especially at night. Prolonged exposure to the sun's rays is to be avoided. The best time to go to Egypt is to arrive there not later than December 1, and go directly to Assouan to remain until the middle of March or

later, after which one may safely go to Cairo by river, and after a short stay at any one of the three stations (Ghezireh, Helouan or Mena House) make his way to Ramleh, where the hotels open April 1, to remain until the time arrives for leaving the country. The best time to leave is about the middle of April.

11. **Strychnin.**—The use of massive doses of strychnin in certain degenerative diseases of the cord, such as tabes, progressive muscular atrophy, optic nerve atrophy and pseudomuscular hypertrophy is advocated by Hammond. He bases his paper on the results of 11 cases, 4 of tabes, 3 of progressive muscular atrophy, 3 of optic nerve atrophy, and 1 of pseudomuscular hypertrophy. The method of action assumed is that the strychnin improves the nutrition of the neurons in such a way as to arrest degeneration. Cases are reported in detail and the results are favorable. In no case, however, was the patient completely restored to health, nor was that anticipated. All he claims for the method is that it may in some cases arrest degenerative processes in disease, which have hitherto been regarded as hopeless. The amounts given by Hammond are large, the maximum dose reaching 2/3 of a grain three times a day, beginning with 1/40 to 1/50 gr.

12. **Surgery of the Esophagus.**—The chief causes calling for surgery of the esophagus are congenital malformations, such as double esophagus or pouches, impacted foreign bodies, malignant disease, syphilis and cicatricial stricture. Congenital malformation Mixter finds more frequent than generally supposed, especially congenital pouches. In many cases he has found the passage of a suitable bougie to relieve the difficulty to a considerable extent. Impacted foreign bodies are best relieved by esophagotomy or gastrotomy rather than prolonged or violent attempts with the forceps and similar instruments, though in the hands of experts these instruments should be first tried. While malignant disease is hopeless of cure, very much can be done to avert starvation and relieve the symptoms. Excision is seldom of benefit, excepting when the growth is very high up and it is possible to bring the lower end of the esophagus into the lower angle of the wound. As a rule we must be satisfied with relieving dysphagia. Dilating a stricture is the most common method of treatment, and is satisfactory in many cases, especially if food is introduced at the same time. For impassable or very irritable strictures esophagostomy or gastrostomy is demanded. Mixter much prefers esophagostomy to gastrostomy in disease high up. Syphilitic strictures are not common and should be treated with proper medication and dilatation. He thinks that the method of Abbe of sawing through the stricture with a string is the greatest improvement in the technic of esophageal surgery of recent years. By Dunham's method of thread swallowing he has been able to relieve the most desperate and apparently hopeless cases of multiple stricture both in children and adults. In conclusion he insists on the greatest care and delicacy of manipulation in all esophageal work.

American Medicine, Philadelphia.

August 29.

14 *The Destruction of Bacteria in Vaccine Pulp with Potassium Cyanid. Harvey R. Gaylord and David E. Wheeler.
15 *The Treatment of Congenital Luxation of the Hips. Gwilym G. Davis.
16 *The Danger that May Lurk in Blind Eyes. Cassius D. Wescott and Brown Pusey.
17 *Enteroptosis: Its Etiology, Symptomatology, Treatment and Prognosis. (Concluded.) Thomas R. Brown.
18 *The Matas Treatment of Aneurisms, with Report of a Case. W. O. Bullock, Jr.
19 The Medical Treatment of Dysmenorrhea. Frank C. Hammond.

14. **Vaccine Sterilization.**—Gaylord and Wheeler have found that a solution of cyanid of potassium, beginning with n/2,000 and extending to n/200, completely destroys the bacteria in vaccine lymph without in any way injuring it specifically. Although potassium cyanid is an active poison it is so volatile that in five to six days no trace can be found in solutions kept in test tubes plugged with cotton in the usual way. It would seem that we have in potassium cyanid a differential germicide capable of killing bacteria without injuring delicate protoplasmic structures. Its application to vaccine strongly suggests that the organism of vaccine partakes of the nature of animal protoplasm and is a protozoön.

15. **Congenital Hip Dislocation.**—David describes the requirements of operation for congenital hip dislocation and gives the history of its treatment. He considers Paci's treatment a real advance and the Lorenz application of extreme force a rather objectionable modification. The results in the properly applied circumduction method, according to the Paci plan, are in nearly all cases good in young children under seven or eight years of age. In older patients the treatment has not yet been thoroughly worked out.

16. **Danger of Blind Eyes.**—Wescott and Pusey call attention to the possibility of involvement of the sound eye in the retention of the blind single eye, reporting a number of histories. They also discuss the relative values of evisceration and extirpation of the eyeball, and conclude that it is hardly possible to destroy all the uveal tissue and that complete removal of the eyeball, according to the present evidences at least, is far safer. Even in children it is advisable. There is good evidence, they say, that the development of the orbit is not materially interfered with by enucleation in childhood.

17. **Enteroptosis.**—This paper is concluded in this number. The author concludes that: 1, in the great majority of cases the underlying cause is a congenital weakness of tissues, which predisposes to this condition; 2, in many cases, probably the majority, various accessory factors favor "a marked displacement of the abdominal organs in those so predisposed." He says:

> Of these factors most act either by increasing the pressure from above on the abdominal viscera, as by the use of corsets, belts, etc., or by decreasing the pressure from below upward, as after severe illnesses, pregnancy, marked loss of weight and strength, etc., while in only a comparatively small proportion of the cases does injury or violent trauma form a part.
>
> As to the symptomatology the undoubted tendency has been to ascribe far too many symptoms to the displacement of certain organs, notably the kidneys and the liver and far too few symptoms to other viscera, especially the stomach and intestines. . . .
>
> As to the proper treatment, far too much reliance has been undoubtedly placed by some on surgical interference. We should recognize that we are treating, in the great majority of cases, a displacement of several of the abdominal viscera, and surgical interference is only justifiable when the symptoms are referrable to an especial displaced organ or when dietetic, medicinal and mechanical treatment have been tried without success. . . .
>
> We should all remember . . . that, by care and watchfulness, we may often do by prophylaxis in the young what treatment, neither medical nor surgical, can do in those in whom the condition has become pronounced.

18. **Aneurisms.**—The Matas treatment of aneurism consists in excision and evacuation of the sac, closing of the mouths of the collateral vessels, scrubbing the interior of the cavity with sterile salt solution and closing the openings with chromicized catgut, sometimes using a second row of Lembert sutures over the first A case is reported which seems to show that a mild amount of infection is not necessarily fatal to success though it does delay the recovery. In addition to the lessened danger of gangrene from not interfering with collateral circulation, the operation has the advantage of preserving every available inch of the artery that is capable of aiding in restoring the circulation in the part beyond. Bullock does not favor the modified operation, aiming to restore the continuity of the vessel in sacculated aneurisms and still less the bridging over the gap in fusiform cases by using the sac wall for the purpose.

Medical Record, New York.

August 29.

20 *The Syphilitic Affections of the Heart and Aorta. Leonard Weber.
21 *Peritonitis (Peritoneal Adhesions) Caused by Muscular Trauma. Byron Robinson.
22 *The Quick and the Dead: A Plea for Urn Burial. W. J. Conklin.
23 *Hydrotherapy in the Treatment of Chronic Diseases. Frederick M. Rossiter.
24 *The Suprapubic Operation for the Radical Cure of Varicocele, with a Report of Eighteen Cases. Robert M. Thornburgh.

20. **Syphilitic Affections of the Heart and Aorta.**—Weber describes the usual course of this condition, calling attention particularly to the deficient blood supply from arterial involvement and its effects on the heart tissues. Myocarditis and subsequent degeneration are consecutive to the vascular lesions. The diagnosis is discussed at some length. The signs of active syphilitic lesions in other parts of the body in cases

of myocarditis go a long way to make the diagnosis certain. He remarks that relying on iodids alone will lead to disappointment, according to his experience, but if mercury is used with them or even without them and the patient's kidneys are sound, the results are good. He has been in the habit of ordering mercurial inunctions whenever practicable; when not, the bichlorid of mercury hypodermically or the biniodid by the mouth. He has found advanced cases of syphilitic aortitis less amenable to treatment than specific cardiac disease.

21. **Peritoneal Adhesions.**—Robinson describes the peritoneal adhesions that he has observed in a large number of necropsies, and which he considers due to muscular trauma. He finds none of these in children that have not walked and practically none under three years of age. The muscular trauma of parturition is mentioned as one of the causes of these adhesions. Their effects are described. They cause about one-third of all obstructions of the intestinal tract, and disorder the functions of peristalsis, secretion and absorption of the intestines, genitals, lymphatics, urinary and vascular tracts, and may entail symptoms that do not indicate their character or location. They increase in frequency from 25 to 65 years of age. Their utility is that they put a barrier on infectious invasion, imprisoning, starving and sterilizing bacteria, and are the great life-saving factors in acute inflammatory processes of the abdominal viscera by preventing peristalsis from disseminating infection, by obstructing the lymph channels leading from the infectious center, as, for example, the subject recovers from relapsing appendicitis more readily because the lymph channels from the diseased appendix are progressively eliminated. They are Nature's method of protection and repair.

22. **Urn Burial.**—The advantages of cremation are reviewed by Conklin, who maintains that for sanitary reasons as well as for many others it is in every way preferable to the usual method of burial.

23. **Hydrotherapy.**—The benefits to be derived from hydrotherapy are dilated on by Rossiter, who enumerates the various methods:

> The shower, the spray, hot or cold; the douche, hot or cold, alternating, and percussion; local or general, named according to area treated; the Brand bath, Bouchard bath, or graduated bath, the neutral bath, half-bath, hip or sitz bath, leg bath, foot bath, arm or hand bath; simple sponging, friction, towel rubs, wet sheet rubs, pail pour, hot or cold compresses, named according to location, alternating compresses, evaporating and non-evaporating compresses, the moist girdle, fomentations, the dry blanket pack, the wet blanket pack, trunk pack, chest pack, hip and pelvic pack, leg pack, wet sheet pack, enemas and effusions. All of these treatments are applicable to the home excepting the Brand bath, the graduated bath, the sprays and the douches.
>
> By the employment of one or more of these measures or combinations the following effects may be obtained: tonic, local or general, sedation, antispasmodic, nutritive, eliminative, diuretic, expectorant, antipyretic, antiphlogistic, hemostatic, emmenagogic, analgesic, vasodilator, vasoconstrictor, hypnotic.

Among the diseases which are benefited by this treatment are gastrointestinal disorders with a chronic tendency, dyspepsia, gastritis and enteritis (which can be decidedly relieved by the author's method), heart disease, chronic nephritis and especially chronic functional disorders. Among the hints he gives is one that the ice bag applied to the precordium at bedtime with cold friction will almost invariably give the patient immediate sleep when insomnia is apparently due to atonic condition of the blood vessels and consequent cerebral congestion in the horizontal posture. For the constipation, which is very common in gastrointestinal disease, he finds the wet girdle one of the most effective measures.

24. **Varicocele.**—The suprapubic operation is described by Thornburgh and a number of cases reported in military practice. The technic according to Girard was followed. It is described in detail, as is also the method of cleansing the hands with chlorid of lime and sodium bicarbonate.

29 *The Effect of Erysipelas on Atrophic Rhinitis, with Report of Case. Lewis S. Somers.
30 Esophagoscopy. Edward A. Aronson.
31 *Indications and Counter-Indications for Prostatectomy. L. Bazet.
32 Moral Insanity or Degeneracy. F. H. Stephenson.

25. **Extirpation of the Bladder.**—This operation may be required in malignant disease, tuberculosis, exstrophy, ureterovaginal fistula following uterine extirpation and in fibroids of the uterus. Hartley has collected 23 cases of complete removal for malignant tumors; 11 performed with intestinal implantation of the ureters, including 6 deaths; 7 with vaginal implantation of the ureters, with 1 death from shock. The total recoveries were 12 out of the 23 cases, or 52.17 per cent. Five patients died during the operation, 3 from collapse afterward, and 4 died a few days later. Vaginal implantation afforded the greatest proportion of recoveries and cases in which the ureters were not involved in the malignant process. The total extirpation of the bladder with implantation of the ureters elsewhere than the vagina gave 43.75 per cent. of recoveries; quite as good as partial extirpation with implantation into the reconstructed viscus. Intestinal implantation gave 6 deaths in the 11 cases. In the male he would advise complete extirpation of the bladder, but it is unsettled whether it is best to extend the ureters into the urethra or into the skin and wear a urinal, or whether we should put them into the intestine. What is offered seems to be in favor of the urethral or cutaneous method, since the deaths in these cases were largely due to avoidable causes. Tuberculosis has been the reason for operating in a number of cases, and Hartley reports 2 here, one in detail, and refers more briefly to the other. Both recovered. For exstrophy of the bladder, the extirpation of the viscus with the implantation of the ureters into the sigmoid flexure or the rectum has been performed 46 times with a mortality of 15 per cent., and 6.5 per cent. of this mortality represents infection of the ureters and kidneys immediately or at some remote period after operation; 8.5 per cent. of the mortality represents shock. The best methods for treating this condition if reconstruction of the bladder is not possible, seems to be either cystectomy with the intestinal anastomosis of Maydl or Pozzi; vesicorectal anastomosis (Frank); extirpation of the bladder and urethral implantation of the ureters (Sonnenburg), or extirpation of the bladder and vaginal implantation of the ureters (Pawlik). The remaining conditions requiring extirpation are rare and did not come under Hartley's observation. He remarks in conclusion that intestinal anastomosis presupposes intact ureters and gives rectal continence, while the vaginal implantation gives slightly better results, but without urinary continence.

26. **Tabes Dorsalis.**—Collins reports one or two of the 140 cases and calls attention to the change of type of disease of later years. He thinks the prognosis is more favorable in the later type, especially since Fraenkel's treatment has been in vogue. That which has a less favorable prognosis is where the stomach is more or less involved. We no longer see the original type of tabes delineated by Duchenne, Romberg and others in which the name "progressive locomotor ataxia" seemed to be so descriptive. The aberrant forms are more common. As to the cause of this change, he thinks no one factor is entirely responsible, but the disease is more generally recognized by the practitioner, and probably treated earlier. We have learned that a certain mode of life, dietary, medicinal treatment, massage, etc., have not infrequently such influence on the disease that the process seems to stop advancing while they are being employed.

27. **Urotropin.**—Coleman finds that the administration of urotropin may be occasionally attended by toxic effects, strangury, etc., which are comparatively frequent if the drug is not properly diluted. The development of toxic effects is not always, or necessarily, correlative with the size of the dose. The individual susceptibility varies greatly. The following symptoms have been observed: Minor toxic actions, such as irritation of the stomach, diarrhea, abdominal pain, a measles-

like rash, headache and ringing in the ears and renal irritation, sometimes with hematuria. The bladder symptoms include strangury, which is the most common effect, and irritant action on raw surfaces in the urinary passages. Eight cases of hematuria have been reported with one doubtful case, to which he adds a case personally observed. In one case hemoglobinuria was associated. The more important of these effects have been reproduced by intravenous injections of formaldehyd. The toxic action of urotropin is evidently due to a special susceptibility to the action of formaldehyd in the dissociation of the urotropin molecule or to interference with the usual disposition of formaldehyd in the body, or to the liberation of an unusual quantity of formaldehyd. The toxic effects of urotropin generally disappear completely within a few days after withdrawal of the drug. A number of cases are reported from the literature and personal observation.

29. **Atrophic Rhinitis and Erysipelas.**—Somers' case was one of atrophic rhinitis of long standing, which completely disappeared after an attack of erysipelas. He has found in the literature but two like cases, both reported by the same observer, Francesco, in the *Revue Hebd. de Laryng. d'Otol. et de Rhinologie*, March 8, 1902. The suggestion is offered that in a small class of cases where ozena has been resistant to all other treatment, it might be well to try an injection of Coley's fluid as a last resort.

31. **Prostatectomy.**—Bazet would postpone the operation when only dysuria and nocturnal incontinence exist, until chronic and almost complete retention, when it will give the best result. In the case of incomplete and chronic retention with a residue of three to six ounces and the use of the catheter three or four times every twenty-four hours, prostatectomy should be employed if the prostate is large. Another indication for prostatectomy is the presence of recurrent calculi. Of the contraindications he considers age the first. Beyond 72 years the chances of success diminish and the benefits of the operation for the short period of remaining life are not proportionate. Infection is another contraindicatory factor, especially when it is accompanied by acute congestion and fever and chronic lesions of sclerosis and renal infection already exist.

39 *Uses of Ergot. Alfred T. Livingston.
40 Scarlatina. F. E. Lambert.
41 *Some Indications for Inducing Abortion and Premature Labor. William P. Pool.
42 Treatment of the Summer Diarrheas of Infants. C. Legrand Kerr.

39. **Ergot.**—Livingston here publishes a paper written a number of years ago, of the same tenor as the one published in THE JOURNAL, March 21, 1903. One of the opinions that he now holds, different from those expressed then, is that ergot acts directly on the fiber of the muscles instead of on their vasomotor centers. In the main the ideas are about the same, proclaiming that ergot is the equalizer of the circulation.

41. **Abortion.**—The indications for abortion are stated by Pool as: Contracted pelvis, in which he advises operation in the thirty-sixth week in suitable cases; chronic nephritis; diabetes; pernicious vomiting (as a last resort); heart disease with aortic murmur, mitral stenosis and cardiac insufficiency; tuberculosis in which possibly curable cases may be made incurable by this physiologic function of pregnancy. He says a woman having an active form of tuberculosis, as evidenced by physical signs and the discovery of the bacillus, should not become pregnant. If conception occurs it would be advisable to terminate the pregnancy at the earliest possible moment.

48 Report of a Case of Thymus Enlargement in an Infant; Sudden Death; Autopsy. Eleanor C. Jones.
49 Report of a Case of Tonsillar Ulcer of Vincent. Lawrence T. Royster.

43. **Kidney Decapsulation.**—The case reported by Rotch was unsuccessful, the child dying two weeks after operation, but still it was of interest as showing a temporary improvement. The death was unexpected, as the patient endured the operation well. The case was an extreme one with serious impairment of function of the kidney, and without the operation death was inevitable in a short time.

44. **Varicella Gangrenosa.**—Edwards calls particular attention to the relations of this condition with tuberculosis, but even here he holds that it is probably due to the ordinary pathogenic organisms. The lack of resistance of a tuberculous patient to infection of all kinds and the probability of his having staphylococci and streptococci already in the respiratory tracts favors its occurrence.

47. **Abdominal Auscultation.**—The value of abdominal auscultation in infants is noted by Shaw, who shows that in young children the respiratory sounds are transmitted and can be distinctly heard well over the abdomen. All adventitious sounds, especially from the lower lobes of the lungs and the lower and diaphragmatic portions of the pleura, are generally so transmitted that they are recognizable, and sounds thus heard are synchronous with respiration and differ from the usual intestinal sounds. His attention was first called to this fact over a year ago in a case of lobar pneumonia. Râles could be heard over the abdomen before they were audible over the chest. Since then he has listened over the abdomen of a large number of infants to determine the diagnostic value of abdominal ascultation.

55 Retinal Hemorrhages in Relation to Degenerations of the Circulatory Apparatus. Thomas A. Woodruff.
56 Modern Surgery of Congenital Cleft Palate in Infancy. S. R. Hopkins.

50. **Traction Injuries of Arteries.**—Wylie notices the injuries of the arteries that may be due to contusions or traction, and suggests that in every case of injury to an extremity, subject to traction or contusion force, the circulation should be carefully noted, and if there is absence or feebleness of arterial pulsation, a careful inquiry should be made to determine, and, if possible, to locate the cause by stethoscopic examination along the exposed part of the vessel for adventitious sounds, etc. He gives cases of injury of the popliteal and axillary arteries and their treatment, which consists in rest and immobilization, external heat and careful watching for the return of circulation. Until artery resection with suture of the entire circumference of the vessel becomes a more practical procedure than it is at present, it offers no hope of overcoming the difficulty. When there is complete death of the part supplied by the arteries, amputation is the only recourse.

52. **Methyl Alcohol.**—Main finds that methyl alcohol is an active and dangerous poison, extensively used in extracts, spirits and medicines intended for internal use, and that its presence is not suspected by the consumer. In this way it has caused death or blindness in numerous instances. He suggests that the Pure Food Commission require every manufacturer to print on the packages the formula of the contents,

and prosecute every one failing to do so. He advocates also a federal tax on methyl alcohol, so that its substitution for grain alcohol would be unprofitable.

63 *Tuberculosis in Animals, with Special Reference to Bovine Tuberculosis. C. A. Cary.
64 Am I My Bother's Keeper? J. R. G. Howell.

57.—This article appeared elsewhere. See THE JOURNAL of August 29, ¶52, p. 580.

59. **Hay Fever.**—Six cases treated by adrenalin are reported by Mertins. In all the patients found it the best thing they had ever used. In three the disease was aborted and in three the symptoms were almost completely relieved. No unpleasant effect or habit followed. He considers adrenalin almost a specific in relieving the conditions.

63. **Tuberculosis in Animals.**—Cary's paper is largely a citation from the literature, and he finds that human tuberculosis can be transmitted to the lower animals and bovine tuberculosis to other animals. There is strong evidence that many infants and older children have contracted tuberculosis from the drinking of milk from tuberculous cows, and undoubted cases of accidental human inoculation with the bovine bacillus have occurred. He believes that tuberculous cows can be kept for breeding purposes if isolated from their own calves and the healthy cattle, and the milk thoroughly sterilized before feeding it to cattle and pigs. They may also be used as food provided the tubercular lesions are few and can be removed without infecting the meat and the meat is thoroughly cooked. All meat-producing animals, especially cattle and swine, should be carefully inspected before their flesh is utilized and all highly infected animals condemned and tanked. Thorough cooking is needed in every case.

67 Veratrum Viride in Puerperal Eclampsia. W. L. Johnson.
68 Malaria: a Review of Some Recent Literature. (To be concluded.) John Zahorsky.
69 *A Therapeutic Suggestion. H. N. Chapman.

65. **Vibration Massage.**—Schmidt recommends the use of vibration massage in prostatic hypertrophy, especially in cases where the usual massage fails and also those where small inflammatory nodules are left after general inflammation. Vibratory massage is applied to each nodule and defines them by their sensitiveness. It can also be recommended in isthmical inflammation combined with old infiltrations in the prostatic urethra and hypersensitiveness of the caput gallinaginis. The best instrument for this purpose is the Benique sound, to which a metal spiral is attached, and vibration given to this with a hammer. He would also advise it in case of simple sexual exhaustion where no infection or inflammation of the prostate exists. The mechanical appliances which can be controlled by electric motors are suggested as the best means for this form of therapy.

69. **Mammary Cancer.**—A therapeutic suggestion of Chapman is to use the *x*-ray for all forms of mammary cancer, not for the treatment of the breast *per se*, but to put the axillary glands in as perfect a condition as possible. When this is done, the cancerous mass should be removed with a knife, but the axillary glands preserved as a defensive barrier. After the wound has healed the glands and breast should be again submitted to the *x*-rays. This suggestion is offered after the experience with and observation of four cases, the axillary glands being removed in each and in each case the final result was disastrous.

75 *Practical Notes on the Diagnosis of Infantile Eclampsia. John Zahorsky.

70.—This article appeared elsewhere. See THE JOURNAL of July 25, title 104, p. 284.

71. **Drugs in Infant Diseases.**—Leavitt's article is a skeptical one as to the value of drugs in diseases of children. He finds that as many cures are accomplished with placebos which contain practically no drugs at all as in energetic drugging. He says he does not mean to be a nihilist as regards medicine, but thinks that the community of children is certainly overdosed. Of a few drugs he makes partial exceptions, such as castor oil and calomel in acute gastroenteric affections and the special use of certain drugs in poisoning, heart failure, etc. Quinin is an antiperiodic and prophylactic in malaria and mercury and potassium iodid useful in syphilis. Antitoxin in diphtheria is certainly a godsend, but there are very few others for which he says a good word.

75. **Infantile Eclampsia.**—The influence of peripheral irritation in producing eclampsia is questioned by Zahorsky, and he thinks that we should sharply distinguish between great irritability of the nervous system due to high fever and to that caused by faulty nutrition. A toxic, circulatory, organic, or functional disease of the brain or meninges must be considered in the diagnosis of cases of convulsion. In his observation in the last few years he has found some constitutional or general disease at the bottom in nearly every case. He does not mean that peripheral irritation should not be sought, but the first question to ask is, what induces the increased irritability?

77 *What the Medical Practice Act Has Accomplished in Ohio. S. B. McGavran.
78 The Development of Obstetric Surgery. James U. Barnhill.

76. **Otitic Suppurations.**—Brown reports several cases of otitis suppuration, 5 of extradural abscess, 1 perisinuous, 2 of sinus thrombosis and 3 of meningitis, all except the last mentioned three surviving, thus bearing out the opinion of surgeons as to the uniform fatality of meningitis in these cases. Nearly all were operated on.

77. **The Ohio Medical Practice Act.**—M'Gavran details the progress that has been made since the passage of the medical practice act, the opposition which it first received and the general good effects that have followed its execution. It has compelled not less than 500 so-called practitioners to give up practice and a good deal more than that number have left the state without attempting to register. Its opponents have been converted to its support. The medical colleges have practically been reformed and the three fraudulent ones that existed abolished. Ohio, instead of being the dumping ground for other states, has been elevated to the very first rank.

105 Report of a Case of a Hermaphrodite. C. L. Hope.

101. **Typhoid Fever in Children.**—Dupaquier has analyzed the reports of the New Orleans Board of Health with reference to the occurrence of typhoid in children in New Orleans, especially of late years. He finds that typhoid may occur at any age, and nurslings are as liable to be infected as older children. Of his twelve cases none of them presented the characteristic temperature curve. The pulse was high from the start with signs of cardiac weakness. The stools were characteristic. The abdomen was hardly tympanitic, none presented hemorrhage or perforation. Roseola was seen in three cases. The spleen was palpable in all, not very enlarged in any. Some cases simulated meningitis. He considers the diazo-test an aid to diagnosis, though not at all pathognomonic. The management of these cases was far from easy; children are not so easy to control and keep in bed. There are probably many cases of ambulatory typhoid in children, he thinks, though their resistance is wonderful. From observation he finds the relation to tuberculosis is decidedly marked; of his 12 cases, 3 died of tuberculosis subsequent to the typhoid attack, and the Widal test proved that they were originally typhoid. It leaves in its wake a condition of anemia which renders the patient susceptible to any infectious disease, thus explaining the relation of typhoid to tuberculosis. All mild cases escape diagnosis. In conclusion he says there are, however, a number of cases of fever, neither malarial or typhoid, which are treated by drugs when all they require is rest in bed and a little dieting.

102. **Empyema in Children.**—The summary of Oechsner's paper is as follows:

1. Physical signs are not always marked—absence of vocal fremitus is an important sign and more or less constant. 2. Exploratory puncture should always be practiced to confirm the diagnosis. 3. The prognosis of pneumococcic empyemata is very favorable. 4. Aspiration should only be resorted to tentatively and as a means of relief in emergencies. 5. In radical operations rib resection is to be preferred. 6. Irrigation should never be practiced unless there be some special indications for same. 7. A diagnosis should be rigidly sought and, once verified, operative measures instituted as soon as possible. 8. In the matter of promoting lung expansion, various devices, such as inflating rubber balloons, blowing soap bubbles, etc., to suit the caprice of the child, which soon tires of any one form of entertainment, should be instituted.

113. **Appendicitis.**—In the case reported by Sherman a pure culture of the Friedlander bacillus was found. This germ was considered the cause of the infection.

114. **Ununited Fractures of the Lower Extremity.**—Wills reports cases of fractures of the lower extremity with skiagraphs, showing the irregularities of union, and calls attention to the futility of any treatment in fractures of the lower end of the femur with turning out of the ends of the bone except incision, freshening ends and suturing with heavy silver wire. He insists on the necessity of immobilization of the leg and thigh on the body by a plaster spica from the toe to the waist and the relaxation of the calf muscles by flexion of the knee to an angle of 45, also the importance of equable pressure about the entire limb, and especially at the seat of fracture.

115. **The Health of College Girls.**—From a study of college girls and school children in the University of California, Ritter holds that the majority improve in health during the four years of college life, that is, those who take their studies seriously and rationally. A college education does not necessarily injure the health of women. The seeds of subsequent ill health are sown at an earlier age and are not the consequence of study. The causes of ill health are mainly traceable to unhygienic living or the sequence of infectious disease. In a large proportion of women students college life, with the mental stimulus of a purpose, improves their health and fits them to become better disciplined and more intelligent mothers. More careful observation on the part of physicians and instructions to parents would, to a large measure, improve the existing unsatisfactory conditions.

2 *A Surgeon's Notes with the Naval Brigade, China. Lloyd Thomas.
3 Some Notes on a Mounted Bearer Company. H. Hathaway.
4 Poverty of Attraction for Man to Become Stretcher Bearers, and the Consequent Inefficiency of that Section. G. Arbour Stephens.
5 Training of Volunteer Bearers and the Position of Regimental Medical Officers. Peter B. Giles.
6 Suggestions Regarding the Personnel, Equipment and Training of Medical Units Attached to Volunteer Infantry Brigades. William Sheen.

1. **The Water Supply in Military Operations.**—Hall describes the various methods of purifying drinking water for landing parties, and concludes that boiling the water is the best. Where this can not be done the Berkefeld filter (sterilized at least once a day) should be used. Chemical methods are practically useless, as they do not for the most part destroy the active bacteria, and are too complicated for men to understand and carry out thoroughly.

2. **A Surgeon's Notes in the China Relief Expedition.**—The surgeon of the British naval brigade, Lloyd Thomas, gives an account of the sanitary aspects of the trip from Tiebtsin to Pekin for the relief of the legations. He remarks on the general neglect of the Chinese as to sanitary matters, but that their wells were an exception, most of them having small elevations built about their mouths to exclude surface water. The principal suffering seems to have been from the heat, and heat stroke was common. A large number of transient cases occurred. Only two of the total number, however, died from this cause. The best treatment was topical applications of water.

15 Bradycardia in Health. Robert J. Blackham.

7. **Sciatica.**—From an analysis of over 400 cases, Bruce concludes that in most cases the primary trouble is in the joint itself. He suggests the following routine in examination:

> Ask the patient to lie down, as he stands in his clothes, on his back or an even firm couch; then, bending the affected limb at the knee, perform the passive movements of flexion, external rotation, internal rotation and extension by Thomas' method at the hip joint of the affected leg. If the case be at all recent one or more of these movements will cause pain, very often sharp pain, as the patient's countenance frequently reveals. Having carefully noted these signs, then ask him to undress and proceed to inspect the gluteal region. With the patient lying flat on his face and relaxing his muscles, you note whether there is wasting in this region or a diminution in the original number of the folds of the nates, and, on comparing those of the opposite hip and the two thighs also together, I venture to predict that in almost every case of sciatica you will discover softening or wasting and flattening of the hip muscles and more or less obliteration of the natal folds of the affected side. With the patient lying on his sound side, you then proceed to inspect the capsule of the hip joint. In some cases you will find it more prominent on the affected side and in a very few (but very seldom, for obvious reasons), you may be able to discover that there is increased heat over the joint. The position of the articulation is best made out by making sure of the exact relation of the anterior superior iliac spine and the highest point of the trochanter corresponding to the joint you suppose to be affected. The next thing to do is to examine carefully and without prejudice the presence or absence of tenderness on pressure over the capsule, . . . keeping in view the fact that the patient is not an impartial witness, so to speak; he is very apt to confound symptoms with signs, and his mind has been so intent on the suffering, say, in his foot, that he refuses to help you in your attempts to discover the important sign you wish to make out, i. e., whether coxal tenderness be present or absent. . . . In many cases moderate pressure with the point of the thumb over some part of the capsule causes so much pain that he winces unmistakably. Of course, to make yourself certain, you compare the two sides and, by all means, follow the line of the sciatic nerve and try to discover whether there is or is not tenderness on pressure along its course.

He describes the anatomy, especially of the nerve supply, and holds that sciatica is some affection of the hip-joint and not neuritis of the sciatic nerve, and that it is connected with the gouty and rheumatic diathesis, and also with so-called non-articular rheumatic arthritis of the hip. The flattening of the glutei and obliteration of the folds of the nates strongly support his contention. We should remember that the nerve supply of these muscles comes not from the sciatic but from the sacral plexus. He asks, on the other hand, why, if sciatica were really an affection of the sciatic muscles, should not the muscles of the whole leg be affected, and why should the wasting and other nerve derangements be localized as we find them, and we have to admit that the electric reaction of degeneration of the muscles is never present, which also is against the neurotic theory. Sciatica rarely, if ever, leads to permanent affections of the nerves and muscles. Many cases, moreover, are aggravated by too early massage, while careful massage and passive movements in the later stage are of the greatest value. The most important thing of all is the fact that in almost every case of sciatica there is lameness. The patient limps when walking, and this he thinks points to the existence of joint disease. There is little difference of opinion, however, as regards the proper treatment. Rest for the articulation is as applicable whether sciatica is of the nature of a neuritis or if the hip joint be the primary cause and antigout and antirheumatic remedies are recommended alike from both points of view.

8. **Appendicitis.**—Moullin points out that the abdominal viscera for the most part are insensitive to pain, and that in inflammation of the appendix the absence of pain is no indication that serious mischief is not occurring. The initial pain of appendicitis, which is commonly referred to the umbilicus, is due to the peristaltic action of the cecum or of the appendix

dragging on the attachment of the peritoneum to the abdominal wall, especially when the appendix is fixed by adhesions. The lessened severity of this initial pain without improvement in the general condition is due to cessation of peristalsis, owing to inflammations having spread to the muscular coat of bowel. The development of local pain, which as a rule precedes by some short time the cessation of umbilical pain, means that the inflammation has spread from the appendix to the parietal peritoneum or to the post-peritoneal cellular tissue, the only structures immediately concerned which are supplied with nerves capable of transmitting painful sensation. The absence of local pain means nothing, and he has more than once operated and found the appendix in a very bad condition, while the patient never had more than a twinge. Severe pain, however, is of serious import, as it implies either wide extent or great severity of inflammation. Deep and superficial tenderness are noted. Both may be present at once. In addition to the deep tenderness which usually exists, there is often a marked degree of cutaneous hyperesthesia, indicating that the corresponding spinal center is receiving from some part of the body unwonted stimuli, and in consequence is unduly sensitive to ordinary impressions. One point of very great importance is that the sudden cessation of this hyperesthesia without any corresponding improvement in the general symptoms, suggests gangrene and immediate operation.

9. **Stokes-Adams Disease.**—Osler's paper is a full account of the Stokes-Adams syndrome, illustrated by the histories of numerous cases and with special remarks on the peculiar characteristics of disease varieties—the post-febrile, arteriosclerotic, neurotic and senile types, special cardiac symptoms, etc. In the late forms the outlook is bad, though in young persons recovery and cure may be expected in a few cases. In such it might be advisable to try the remedies that may have an influence on the sclerosis, such as iodid of potassium in syphilis, and, with high tension, the nitrites. In senile cases with vertigo he thinks it is doubtful whether we can do more than keep the bowels open and regulate the diet. We have no remedy at our command which will accelerate a permanently slow pulse. A quiet, well-regulated life helps to ward off attacks of vertigo and syncope as in angina pectoris. In spite of the utmost care life may be a burden with the recurring seizures. For the syncopic attacks nitrite of amyl and strong ammonia may be used, and they may often prevent an attack if there is a warning. Brandy, ether and strong cardiac stimulants may be required to revive the patient in the protracted attack. The epileptiform and pseudo-apoplectic attacks may sometimes be prevented by posture. With signs of heart dilatation and many abortive systoles and infiltration of the bases of the lungs, digitalis may be cautiously tried.

12. **Aspirin in Chorea.**—This drug has been employed in 35 consecutive cases of chorea in outpatients at the Ancoats Hospital and the Manchester Royal Infirmary by Williamson, and the details of 8 cases are given. Among these 35 cases there were some of long duration where the symptoms proceeded unchanged, and every means had been tried without effect until this drug was given. In some mild cases very slight medication will sometimes help, and the fact of their doing well under aspirin is not so significant, but in the severe cases like those referred to, it seems of some importance. He can not regard it, he says, as a specific for chorea, but the results of its administration are so favorable as to indicate the probabilty of a beneficial action of the drug, and to suggest further observations.

19 *Note on the Mycoid Body Found in the Blood Corpuscles in Remittent Fevers. (Continued.) W. Leonard Braddon.

19. **Remittent Fevers.**—Braddon holds that the mycoid bodies found in cases of remittent fever are not the relics of blood plates, but are true parasites, many of them containing masses exceeding that of the original enclosing red corpuscles. To what class of organisms they belong he thinks is uncertain. He suggests, however, from the hypha-like appearance of the filaments, their mobility at certain stages and their final apparent contraction recalling the true plasmodium of certain fungi, that their place may be among mycetozoa.

21 Eosinophilia Associated with Dracontiasis. Leonard S. Dudgeon and F. J. Child.
22 *Yellow Fever and Mosquitoes. Ivo Bandi.

20. **Mosquitoes in Steamers.**—Balfour calls attention to the fact that the bilge water of steamers is often swarming with the larvæ of mosquitoes, and that attention should be given to this fact. A ship-bred mosquito might very well pay a flying visit ashore and come back infected and spread the epidemic in its accustomed quarters.

22. **Yellow Fever and Mosquitoes.**—Bandi offers a criticism on the theory of yellow fever transmission by mosquitoes, calling attention to the fact that the *Stegomyia fasciata* is a day biter, and yet in Rio Janeiro those who pass the nights outside the infected limit escape the disease. If the *Stegomyia fasciata* were the sole transmitter of the disease it is difficult to see how spending the nights away from its haunts would secure an immunity.

33. **Foreign Bodies in Nerve Cells.**—Marinesco found crystals in the nerve cells in the cadaver of a woman succumbing to a hemorrhagic meningitis. They responded to the tests for hematoidin. He has also discovered lepra bacilli in the nerve cells of the spinal ganglia. These phenomena might be accepted as evidences of ameboid movements on the part of the nerve cells, but Marinesco does not believe that this is the true explanation. He thinks that the hematoidin probably entered the cell in a saturated solution, and was precipitated in the form of crystals on encountering substances in the cell endowed with a catalytic action. He believes that bacilli may be swept into the nerves by the lymph stream. He has never discovered them in the cylinder-axes.

34. **The Tuning Fork in Medical Diagnosis.**—Mignon calls attention to the varying resonance of the internal organs and tissues transmitting the vibrations of a tuning fork applied to the skin above them. He uses the phonendoscope with the tuning fork and states that important information may thus be derived in examining the sinuses, lungs, skeleton and various organs.

39. **Attempts at Leuco-Therapy.**—Labbé reviews the various experimental work that has been done in the line of inducing hyperleucocytosis in animals as a protection against infection. He shows that the induced hyperleucocytosis, while theoretically a powerful means of aiding the natural defenses, is in practice able to confer a preventive protection only, and seems to be powerless against already established infection. At the same time, he adds, the hyperleucocytosis induced by nuclein—which is the substance that has been most generally employed—is possibly not intense enough for the desired purpose. It is not to be compared with the hyperleucocytosis induced by disease germs. When we have learned some more efficient means of inducing hyperleucocytosis in animals, it is possible that the results of this leuco-therapy may be applied to man with success.

41. **Michel Clamps for Fastening the Permanent Catheter.**—The little clamps or agrafes invented by Michel for suturing the skin are being used more and more in France and this country. The latest use to which they have been applied is to hold the permanent catheter in place, a thread around the catheter being tied to one of the clamps stuck into the skin.

43. **Chemical Diagnosis of Hyperchlorhydria.**—Meunier announces that the determination of the total acidity and of the free hydrochloric acid is not sufficient to diagnose with certainty a hyperchlorhydric gastric juice. In 20 cases he found that the soluble substances derived from starch after an Ewald test meal varied from 4 to 8 gm., while in 15 normal subjects the amount of these substances ranged from 20 to 88 gm. He thinks it is evident that the power of digestion possessed by the mucosa is of more import than its secreting power. He does not classify a gastric juice as hyperchlorhydric unless after an Ewald test meal it contains less than 10 gm. per 1,000 c.c. of sugars reducing Fehling's solution. Or to state it still more precisely, unless it contains in solution soluble substances derived from the starch, which after transformation into dextrose show a lesser amount of the latter than 20 gm. per 1,000 c.c. Determination of hyperchlorhydria on this basis not only confirms the diagnosis but indicates the proper dietary.

44. **Technic of Gasserectomy.**—Juvara illustrates with numerous cuts the various steps of gasserectomy by the spheno-temporal bone plane route, with the eight instruments required. He performed it recently on a patient with intractable trifacial neuralgia, after numerous experiments on the cadaver. The technic differs very slightly from that followed by Quénu, Sébillot and Poirier.

47. **Splenectomy in Banti's Disease.**—Roger reports 2 cases and emphasizes the fine results that may be obtained from this measure even in advanced cases of this syndrome, which includes enormous hypertrophy of the spleen, hypertrophy of the liver, ascites and low hemoglobin rate. (The untimely death of Dr. Roger was chronicled last week.)

50 and 53. **Excision for Diagnosis in Leucoplasia.**—Gaucher insists on the danger and uselessness of this measure in case of cancer of the tongue. He believes that it is liable to entail a terrible exacerbation of the lesion. Diagnosis is easy without it, he claims. Epithelioma is an isolated, single tumor. In sclerosis, if the ulceration is single, there are other protuberances and multiple fissures. Both sclerosis and gumma, he states, are always located on the upper surface of the tongue, while cancer sometimes occurs on the under surface. Epithelioma forms a harder, more hemorrhagic ulceration; there is a fetid exudation, and the pain, salivation and interference with movements are much more marked than in case of ulcerative sclerosis, while the glands never become enlarged with mere sclerosis or gumma.

55. **Tests of Foods.**—Martel concludes his review of the technic for detecting adulterated and unhealthy foods, with a description of the biologic blood test applied to the differentiation of horse meat from other meats. The precipitating reaction is absolutely specific for pork, horse meat and dog flesh, but beef and mutton may respond indifferently to the test.

56. **Simple and Rapid Means of Purifying Drinking Water.**—Vaillard and Georges utilize iodin as an efficient means to destroy disease germs in the water. They neutralize it afterward with sodium hyposulphite, which combines with the iodin to form sodium iodid, which is harmless, even in much larger amounts than are required for the sterilization. According to the technic they recommend, the chemicals are put up in the form of three colored tablets. The formula for the first is as follows: dry potassium iodid, 10 gm.; dry sodium iodate, 1.560 gm., colored with methylene blue. Tablet No. 2 contains only 10 gm. tartaric acid colored with sulpho-fuchsin, and tablet No. 3 merely sodium hyposulphite, 11.6 gm. Each of the formulas makes 100 tablets. The sodium iodate gives up its iodin in contact with slightly acidulated water and the potassium iodid maintains the nascent iodin in solution. A blue and a red tablet are dissolved in a quart of water, stirring well. The water turns a brownish yellow. This mixture is then poured into the 10-liter vessel full of the water to be purified, which turns yellow. After waiting ten minutes, dissolve the white (hyposulphite) tablet in another quart of water and pour this also into the large vessel. The water loses its yellow tinge at once and becomes limpid and is ready to drink without further delay.

59. **Medication in Chronic Disease.**—Hayem thinks that medicines frequently prevent the benefit that might otherwise be obtained from hygienic and dietetic measures in chronic diseases, especially in tuberculosis. The digestive tract must be spared every source of irritation or fatigue. In his experience the suppression of all medication has frequently abolished all tendency to gastric crises in tabes. He is even inclined to admit that medicinal intoxication is the habitual cause of the nervous forms of chronic affections and possibly also of the nutritional disturbances, cases of cancer excepted.

61. **Therapeutics in Extremis.**—Lejars regards saline infusion as the most efficient weapon at our disposal when death seems imminent. He relates 2 cases in which after actual bleeding to death warm saline infusion was able to bring back a slight color to the lips, the heart began to beat after ten minutes' arrest, the respiration was gradually re-established, consciousness returned and the patient survived twenty-four hours. In both of these cases death was due to the loss of the vital fluid, the vessels, being empty, were unable to act, but when filled with the saline solution they resumed their function, and if the patients had had a little more vitality left, they could have been saved. De Ott has demonstrated that regeneration of the blood occurs twice as rapidly under the influence of saline infusion as of transfusion of blood. Lejars believes in operating in cases of peritonitis, etc., even when the patient is apparently in extremis, and reports several cases in which the most unexpected success was realized. In one of umbilical pseudo-strangulation with eight days of stercoremic intoxication, the skin marbled with purple, the extremities cold, with regurgitation of fecal matters, the hernia enormous, red and tense, he operated under cocain, sustained by the fact that the breath did not have agonal fetidity and that the pulse, although small, was still perceptible. The patient made a smooth recovery. Progressive depression, irregularity of the heart action and anuria are important indices and also the cyanosis and pronounced hypothermia which indicate that the bulbar centers are poisoned beyond relief by the bacterial toxins. The toxic impregnation at this stage is too advanced for any intervention to have a chance of success, but there is always a chance until this point is reached. Operations in these advanced stages of septicemia, peritonitis, etc., must be simple, short, and be done without general anesthesia. The heart must be guarded above all. Here, again, saline solution by rectum or subcutaneously is the sovereign resource. If the serum does not induce diuresis it is because the kidneys are already fatally compromised and the end could not have been averted. The absence of diuresis thus becomes a valuable sign for the prognosis.

64. **Trunecek's Serum in Ear Affections.**—In a thesis recently presented at Paris Sari describes 16 cases of sclerosis of the middle ear, the labyrinth syndrome or sclerous otitis, treated by subcutaneous injection of Trunecek's serum every second day, the amount varying from 1 to 6 c.c. The symptoms due to the labyrinth (vertigo, sounds in the ear or deafness), were rapidly improved or cured by a small amount of the serum, and transient or permanent success was also obtained in cases of sclerosis of the cavity of the tympanum or labyrinth. On the other hand, those with sclerosis and adhesions consecutive to suppuration were not only not benefited, but in some the symptoms were aggravated by this treatment. The formula for the serum was given in THE JOURNAL, xl, page 874.

72. **Distomiasis.**—Inouye reports that in his examination of subjects in various regions of Japan he found eggs of this parasite in from 19 to 71.9 per cent. of the feces examined, the number of subjects in each locality thus examined ranging from 47 to 725. About 71.8 per cent. of his 2,460 patients with distomiasis were males. Regions most affected are those where malaria also prevails. He reviews the symptoms, etc., remarking that treatment can be only symptomatic. Antiparasitic drugs have proved useless. In prophylaxis he warns against drinking or swimming in canal water or eating raw fish or mussels. In one region the mortality from this source has been reduced to zero by such precautions.

75. **Rectal Stenosis and Parametritis.**—Mueller reiterates his former assertions in regard to the frequent causal combination of these affections, the second being secondary to the first. He points out that the sacro-uterine ligaments embrace the rectum, and every inflammation of the latter, especially chronic ones, shorten and stiffen these ligaments. This reacts on the intestine, which becomes constricted, kinked and forced against the sacrum. The uterus may be drawn out of position likewise. He thinks that this rectal origin of gynecologic affections is more common than the gonorrheal, and frequently dates from early life. Childbearing may serve as a vigorous massage to aggravate or relieve the condition. In the former case, the pregnancy is usually regarded as the primary cause. In diagnosing gynecologic affections it is wise, therefore, to test the elasticity of these ligaments, and seek for traces of inflammation in them and in the rectum. Infection of the vicinity from the constricted and possibly ulcerated bowel is more than probable. The hardened ligaments must be softened by warm irrigations, sitz baths and cataplasms, and when loosened, their elasticity must be restored by stretching, and the stenosis combated by massage. Pessary treatment later will promote the restoration of elasticity, but should not be commenced until the inflammatory stage is past.

76. **Ehrlich's Indol Test.**—Baumstark applies the dimethylamido-benzaldehyd test by an original method, which he calls the "extinction method." It consists in diluting and examining the solution of indol after applying the test, comparing it with a control solution until the band in the spectrum characteristic for the mixture vanishes. The indol mixture gives a well-defined band in the spectrum between D and E, commencing at the former, and skatol gives two bands, one at this point and one between C and D. Solutions of various concentration give, of course, bands of varying distinctness, until the dilution reaches a point when the bands are no longer visible. He found that solutions of indol and skatol after applying the reagent rapidly change color. He does not attempt to use an instrument of precision, but finds the pocket spectroscope perfectly adapted for the purpose. He tabulates the findings in applying the test thus modified on various subjects, and extols in high terms the value of this new method of quantitative investigation of the indol. The test is simple, easy, takes very little time, and places in the hands of the internist a method of determining the absolute amount of indol in the feces and urine. In estimating the total putrefaction of albumin in the intestines, the indican and ethereal sulphates in the urine and the indol in the feces must all be determined. He states that in cases of obstipation, achylia, hyperchlorhydria, pernicious anemia and chlorosis the indol was increased to a moderate or extreme extent in his experience, while it was reduced in diarrhea and in one case of achylia. Certain cases exhibiting severe symptoms showed an enormously increased proportion of indol in the urine, while in the feces it was reduced. Such contrasts as these have hitherto escaped observation. As it is impossible to assume increased absorption in these cases, owing to the seriously compromised condition, the explanation must be the loss of the normal oxidizing power for the products of putrefaction that are absorbed. His experience also establishes that the disturbances in the digestive tract coexisting with achylia and hyperchlorhydria are liable to have an unfavorable influence on the putre-

faction of albumin, although it is impossible to ascribe to the hydrochloric acid any direct disinfecting power beyond the confines of the stomach.

77. **Determination of Albumose in Feces.**—Ury emphasizes the necessity of extracting the substances in the feces which mask the biuret reaction before attempting to determine the albumose. Besides the urobilin, there is a brown pigment which must be eliminated. It is necessary also to extract the substances which respond, themselves, to the biuret test. This includes both urobilin and nucleoproteid and remains of casein. The albumin in solution in diarrheic stools must also be eliminated.

79. **The Sahli Test of Stomach Functions.**—THE JOURNAL has described Sahli's "flour soup" test as a means of determining the state of the gastric functions. (See xxxviii, page 1477.) The present article reports experiences with it in a Vienna clinic. The writers have become convinced that it is too complicated for general use in practice, but that in cases of nervous dyspepsia it may prove of great value. It is especially useful in differentiating atony from alimentary hypersecretion, which it accomplishes with an exactness hitherto unattainable.

86. **Anti-Bacterial Diphtheria Serum.**—Bandi believes he has established that the specific bacterial agglutinins of a serum must be regarded as true bactericidal substances. The degree of the agglutination and "sensibilization" is, therefore, the index of the bacterio-toxic action of a specific serum *in vitro*. The specific agglutinating power parallels the phases of the immunizing process against the bacteria, as likewise the sensibilizing power. Tests of the standard diphtheria antitoxin from Paris, Berne and Brussels failed to show any of these specific agglutinating and sensibilizing properties. Bandi reports success in the clinic with an antidiphtheria serum produced with a view to secure as much as possible of these properties. He adds a specific antitoxic serum to cultures of the diphtheria bacilli. The bacilli take up from the serum the substances which are specifically toxic for them. The serum is then centrifugalized out of the culture, and the bacilli thus "sensibilized," as he calls it, are injected into a goat in amounts which would be fatal if they had not been thus previously sensibilized. The injections cause intense phagocytosis and the serum of the animals acquires pronounced specific agglutinating and sensibilizing properties. It has very little antitoxic action, but it is rich in antibodies and has remarkable curative effects. He suggests that a combination of this serum with ordinary antidiphtheria antitoxin might prove useful in practice. His researches were conducted at the Brazilian National Institute of Bacteriology, and he reports in detail 2 out of the 7 cases treated on these principles. The results were so fine that he did not consider it necessary to wait for further experience.

96. **Therapeutic Preparation of Bacteria.**—Marpmann cultivates the tubercle bacilli in milk to procure the specific substances which the bacilli elaborate, and he then administers them by the mouth to tuberculous patients. He gives a cut of the apparatus he has devised for the purpose to allow a constant circulation of air and current in the milk, which becomes entirely impregnated with the bacterial cultures. They are then transferred to a medium, of which he gives the formula, and the bacilli and medium are frozen together, ground and mixed with alcohol. Five drops of the fluid thus obtained are given to the patients three times a day. A number of practitioners are now testing this remedy in their practice, and the results will soon be published in detail.

101. **Diagnosis of Cholera.**—Kolle remarks that genuine Koch cholera vibriones were found in 59 out of 73 cases of cholera examined last year in Egypt. In 14 the micro-organisms derived differed from them, and possibly the diagnosis may have been erroneous in some. The agglutination test proved again its specificity in more than 1,000 tests with

various combinations of germs and serum made with the true and the false cholera vibriones. He advises eight hours of "peptone water pre-culture" and eight hours of agar plate culture, the agglutination studied in the hanging drop with 80 magnifying power, dilution 1 to 1,000. This allows an exact diagnosis in sixteen hours.

102. **Myelogenic Tumors.**—Bloch relates a case in detail which establishes that it may be possible by examination of the blood to diagnose a myelogenic tumor before any characteristic symptoms have developed. The patient was a man of 41, presenting symptoms suspicious of a neoplasm in the spine. The abundance of myelocytes found in the blood indicated that the bone marrow was under the influence of some irritation. The spleen was unusually large and soft, and there was fever. The necropsy revealed a spindle-celled sarcoma originating in the vertebræ. Bloch describes several other cases with unusual and interesting blood findings.

104. **Diabetes and Cutaneous Affections.**—Saalfeld's experience emphasizes the importance of combining both general and local treatment in case of this association of diabetes and skin disease. In 2 instances the latter developed first as a premonitory symptom of the diabetes. One was a case of acne necrotisans corporis, the other pruritus scroti. He found that ordinary skin diseases in diabetics, rebellious to the usual measures, yielded to them after constitutional treatment had been instituted. He had this experience in several cases of eczema, pediculosis pubis, acne rosacea, lichen ruber, ulcus molle, ulcus cruris, etc. When these affections proved intractable he found that change to an antidiabetic diet was soon followed by a cure of the skin lesions. This was also peculiarly his experience with pruritus, and to such an extent that he now examines the urine as a routine measure in every case from the start. He never found glycosuria associated with psoriasis or leucoplakia oris, but mentions that neuralgic pains were exceptionally severe in his diabetic patients.

105. **Treatment of Ankylostomiasis.**—Nagel practices at Bochum, a hotbed for this affection; 4,000 patients have been treated in the hospital since '96. Kraft has been able to isolate from ext. filicis a non-toxic essential principle which Nagel believes to be the true effective worm-expelling element. He calls it "filmaron" and reports that it is proving in the clinic all that had been anticipated for it, succeeding in 9 cases after failure of extractum filicis. His experience suggests that the male fern does not kill the worm but merely benumbs it, and that the following purgative is the real expelling force. Ankylostomiasis is spreading in the mines of the region as the miners know of cases of sudden blindness that have followed treatment, and shrink from applying to a physician. Nagel himself has observed 2 such cases, the robust men becoming totally blind after ingestion of 10 gm. of extractum filicis in one or two doses. The discovery of the non-toxic, effective element in the drug, therefore, is of great importance.

106. **Albumin Test in Diagnosis of Cancer of Stomach.**—Salomon's test is based on the exudation of serum from any cut or ulcerating surface. He prepares the patient for the test by giving fluid food only, free from albumin, such as coffee, wine, bouillon, tea, the day beforehand. At 9 p. m. the stomach is rinsed until the rinsing water returns clear, and the patient is warned not to eat anything more. The next morning 400 c.c. of normal salt solution is poured into the stomach and then siphoned out and poured in again and siphoned out once more, to give the stomach as thorough a rinsing as possible. The siphoned-out fluid is then tested for nitrogen by the Kjehldahl method, and the Esbach test for albumin applied. He reports experiences with 22 patients, which showed that the Esbach test was negative in 6 cases of gastric catarrh, or only faintly positive; absolutely negative in 5 of nervous dyspepsia, and negative or faintly positive in cases of other gastric affections, with the exception of cancer. In 8 cases of carcinoma of the stomach the Esbach findings were decidedly positive, showing the presence of 1/16 to 1/2 per 1,000 of albumin in every case. He thinks that a negative reaction may aid in excluding cancer in dubious cases, to say the least, and that a marked positive reaction under certain restrictions may confirm the diagnosis. The nitrogen was also more abundant in the cancer cases, ranging from 10 to 70 mg. in 100 c.c. of fluid. When the siphoned-out fluid shows a flaky turbidness or the nitrogen is over 20 mg. in 100 c.c., cancer may be suspected.

109½. **Reduction of Polyuria by Strychnin Hypodermically.**—Feilchenfeld announces that a daily injection of .005 gm. strychnin nitrate proved effectual in reducing the amount of urine in a severe case of polyuria and one of diabetes insipidus in his experience. The urine dropped from 3,200 gm. to 1,400. The specific gravity does not seem to be altered, and this, with the promptness of the response, impels him to ascribe the action of strychnin in these cases to an influence on the central nervous system.

111. **Clinical Tests for Urobilin.**—Schlesinger reports from Nothnagel's clinic that it is possible to obtain fluorescence from urobilin in urine and distinct bands in the spectrum if an equal amount of a 10 per cent. alcoholic solution of zinc acetate is added to the urine and the precipitate filtered out. Usually this fluorescence and the spectrum bands are masked by the presence and action of other pigments, but by this procedure even a very small proportion of urobilin with large proportions of the other pigments responds perfectly to the test. Hemoglobin disturbs the reaction and the technic must be modified for blood. For this he measures 1.5 c.c. of a .7 per cent. saline solution and adds enough potassium oxalate so that when the same amount of blood is added a 1 per 1,000 solution of the oxalate results (.5 potassium oxalate to 200 saline solution), then adding 1.5 c.c. blood drawn fresh from the finger. The oxalate prevents the coagulation of the blood without disturbing the reaction. The tube is then centrifugalized, the clear fluid decanted and poured into the same amount of the alcoholic zinc acetate and centrifugalized again. The supernatant fluid is then examined for fluorescence and the spectrum bands.

120. **Life-Maintaining Action of Stimulus.**—Schücking, in continuing his researches on the eggs of the starfish and other echinoderms, has found that stimuli of various kinds are able to confer greater resisting power on the cell, enabling it to survive the action of substances which destroy the control cells. The shriveling of the living protoplasm in hyperisotonic solutions he believes to be a process independent of osmosis, a reaction of the living substance. He has become convinced that the cell is able to regulate its intake and outgo of water independently of the osmotic differences of normal metabolism. His experiments with chemical, electric, mechanical and other stimuli are described in detail.

121. **Stain Differentiation of Blood-Plates.**—Preisich and Heim exhibited at the meeting of the local medical society, March 28, a number of stained specimens of blood-plates which show them up in a new light. They followed the Romanowski technic, slightly modified, and claim to have established with it that the blood-plates are nucleated formations of the red corpuscles thrown out by the latter into the circulating blood. They frequently found the red-stained blood-plates inside the blue-stained red corpuscles. In morbid processes accompanied by much regeneration of the red corpuscles, the number of blood-plates was correspondingly increased, while it was low in pernicious anemia. They also found blood-plates occasionally inside the phagocytes. The granulations of the latter may be merely the granulations left from phagocyted blood-plates. In size, staining reaction and other points they seem to be identical with the granulations of the blood-plates.

129. **Albuminuria with Insufficiency of Aortic Valve.**—A young man with the clinical picture of insufficiency of the semilunar valves, exhibited likewise symptoms of connective tissue induration of the kidneys. The necropsy showed similar induration in liver and spleen, while the lungs were exempt. The case demonstrates that in case of insufficiency of the aortic valves, albuminuria may be observed, not only as an expression of venous congestion in the kidneys, long before any other signs of this congestion are apparent, but also as a manifestation of general atheromatosis in its most restricted sense —the same affection which develops primarily in elderly subjects, but which in these conditions is the direct result of the valvular affection. The maximal increase in the blood pressure and its fluctuations in the vessels and capillaries in the kidneys, entail a thickening of their walls and a proliferation of connective tissue in their vicinity. The induration in the kidney may be regarded as arterial induration in contrast to cyanotic induration. As the circulation in the organ suffers, albumin and later even tube casts may be found in the urine. The date of the appearance of the induration and albuminuria depends on the intensity and duration of the valvular affection.

133. **Transplantation of Sartorius in Old Fractures of Patella.**—Schanz has treated a case of old fracture of the patella with an unsurmountable gap, by digging a continuous groove in both fragments and transplanting into this groove the isolated sartorius muscle, suturing it in place with wire. He asserts that by this method it is possible to restore function to old fractured patellas, no matter how wide the gap. If there is the slightest tendency to the formation of a fibrous callus the joint need not be opened at all. Another advantage of the measure is that the quadriceps is strengthened and the disposition to atrophy averted.

136. **Joint Affections in Hereditary Syphilis.**—Hippel affirms that joint affections are frequent in hereditary syphilis, and especially among those subjects who were not treated with mercury in childhood. Hence they are often observed in subjects presenting keratitis, as these are mainly recruited from this class. In 56 per cent. of 77 patients with syphilitic keratitis in his practice since 1885, he was able to discover some joint affection, and in nearly every instance it had preceded the ocular affection. In several cases its syphilitic nature had been unsuspected, and it had been treated by eminent surgeons on some other basis. The functional disturbance was generally slight, and only in a few instances was the subject confined to bed. The knee was almost invariably the joint affected, sometimes accompanied by swelling of the elbow, wrist or finger joints. The prompt benefit derived from potassium iodid differentiates these cases. He examined a number of non-syphilitic eye patients and found that joint affections were rare among them, while in his total of 85 cases of keratitis in syphilitics, the joints were or had been affected in 47. The joint affection is usually merely a serous or sero-fibrinous effusion in the knee, bilateral, without preceding trauma and generally without fever; causes remarkably slight subjective disturbances and usually heals in time without permanent functional derangement.

137. **Tardy Hereditary Syphilis.**—Jordan publishes an account of a case of tardy congenital lues in a young soldier, localized solely in the knees. The success of treatment confirmed his diagnosis of miliary gummata in the synovialis. He adds a second case, a child with a gonitis proceeding from the knee joint and associated with keratitis parenchymatosa. He adds that in all cases of mild bilateral knee affections in children or adults a dubious diagnosis may be cleared up by instituting specific treatment. It must be energetic and long continued to effect a cure in these hereditary cases.

138. **Inheritance of Syphilis.**—It is possible, von Düring reasons, that syphilitic infection may occur and its manifestations remain limited for a time to interstitial inflammation of the internal organs, escaping our diagnosis. Such a latent syphilis would explain the cases of tardy hereditary syphilis and also the syphilis of apparently sound mothers of children with hereditary syphilis. Matzenauer believes that the mother of every child that proves to have an inheritance of syphilis must herself be infected, and should receive specific treatment irrespective of the apparent soundness of her health. He rejects the idea of spermatic infection, and thinks that if the placenta is sound the children will be free from syphilis. These views require confirmation, and it is important that family physicians should aid specialists in this research, following for years both mothers and children in these puzzling cases. Examination of the placenta is particularly important from this point of view, and study to determine the specific alterations in the placenta, and whether it is possible that the fetal or maternal portion might be alone involved. For the present the burning question is as to whether the apparently healthy mothers of syphilitic children are actually sound or are they infected.

140. **Outlining the Heart with the Phonendoscope.**—Moritz has repeated Smith's examination of the heart with the phonendoscope, but his findings do not agree with those obtained by Smith. He gives numerous cuts to show that it is physically impossible for the latter to be correct.

141. **Etiology of Gastritis Phlegmonosa.**—Gastritis phlegmonosa occurs most frequently in men, and besides excesses, trauma, intoxication and irritating food as the cause, it may be due to the invasion of the submucosa of the stomach by pus cocci. There are 67 cases on record and Klieneberger now reports another. He attributes the etiology in this case to the simultaneous administration of potassium iodid and calomel to a patient, a man of 67, suffering from acute exacerbation of chronic bronchitis, with emphysema. He had never presented any symptoms of gastric derangement and he took only 3.5 gm. of the potassium iodid in all. It was suspended as symptoms of iodin intoxication developed, including severe gastric disturbances. Eight hours after the last dose of the iodid .3 gm. of calomel was given. The patient died in thirty-six hours, and at the autopsy diffuse phlegmonous gastritis was discovered.

142. **Gonorrheal Affections of the Eyes in Adults.**—The case described was distinguished by the metastatic affection in the eyes after six years of latency, and simultaneous involvement of all the joints and the tendon sheaths of one foot.

143. **Fate of Tubercle Bacilli in Heated Milk.**—Rullmann announces that tubercle bacilli heated in milk to 65 C. (150 F.) for more than thirty minutes, were still virulent enough to infect guinea-pigs in intraperitoneal inoculation. The milk was infected with sputa.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

PRACTICAL MEDICINE SERIES OF YEAR BOOKS. Comprising Ten Volumes of the Year's Progress in Medicine and Surgery. Under the Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Postgraduate Medical School. Volume VIII. Materia Medica and Therapeutics, Preventive Medicine, Climatology, Suggestive Therapeutics and Forensic Medicine. Edited by George F. Butler, Ph.G., M.D.; Henry B. Favill, A.B., M.D.; Norman Bridge, A.M., M.D.; Daniel R. Brower, M.D., and Harold N. Moyer, M.D. Cloth. Pp. 326. Price, $1.50. Chicago: The Year Book Publishers. July, 1903.

QUANTITATIVE CHEMICAL ANALYSIS. Adapted for Use in the Laboratories of Colleges and Schools. By Frank Clowes, D.Sc. Lond., Emeritus Professor of Chemistry in the University College, Nottingham, and S. Bernard Coleman, A.R.C.Sc. Dublin, Professor of Chemistry in the Southwestern Polytechnic, Chelsea, S. W. Sixth Edition. Cloth. Pp. 602. Price, $3.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

TREASURY DEPARTMENT. Public Health and Marine-Hospital Service of the United States. Hygienic Laboratory—Bulletin No. 15. Inefficiency of Ferrous Sulphate as an Antiseptic and Germicide. By Allan J. McLaughlin. Paper. Pp. 7. Washington: Government Printing Office. 1903.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, Aug. 29, 1903:

Heizmann, Charles L., colonel and assistant surgeon-general, and Major Willim H. Arthur, surgeon, are detailed as members of the board of medical officers appointed by paragraph 26, S. O. 65, March 19, 1903, A. G. O., for the examination of candidates for admission to the medical corps of the Army, vice Brigadier-General Calvin DeWitt, U. S. A., retired, and Major Louis A. La Garde, surgeon, relieved.

McCulloch, Jr., C. C., captain and asst.-surgeon, in addition to his present duties as attending surgeon and examiner of recruits in New York City, is assigned to duty as medical superintendent of the transport service in that city.

Porter, R. S., first lieut., is detailed as a member of the examining board at Fort Leavenworth, vice First Lieut. W. M. Smart.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Aug. 29, 1903:

Asst.Surgeon E. M. Brown, detached from the Naval Hospital, Newport, and ordered to the *New York*.

Surgeon M. S. Elliott, detached from the *New York* and ordered home to wait orders.

Surgeon N. H. Drake, detached from the *New York* and ordered to the *Maine*.

Surgeon D. O. Lewis, ordered to the *New York* as fleet surgeon of the Pacific Squadron.

P. A. Surgeon H. C. Curl, detached from the Naval Hospital, Mare Island, Cal., and ordered to the *New York*.

Surgeon W. R. DuBose, detached from the *Maine* and ordered to duty in the Bureau of Medicine and Surgery.

Surgeon J. F. Murphy, detached from the *Monocacy* and ordered to the *Wisconsin*.

Asst.-Surgeon J. C. Thompson, detached from the *Chesapeake* and ordered to the Naval Academy.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Aug. 20, 1903:

Surgeon C. E. Banks, granted three days' leave of absence from August 8, under paragraph 189 of the Regulations.

Surgeon D. A. Carmichael, Bureau order of Aug. 10, 1903, directing him to report to director of laboratory for special instructions, amended so that he shall report at the laboratory for temporary duty.

P. A. Surgeon J. C. Perry, relieved from temporary duty in the Bureau and directed to report to the director of the laboratory for duty.

P. A. Surgeon M. J. Rosenau, granted leave of absence for seven days from August 19.

P. A. Surgeon J. A. Nydegger, granted leave of absence for one month from August 13 on account of sickness.

P. A. Surgeon H. W. Wickes, leave of absence for one day granted by Bureau telegram of August 13 revoked.

P. A. Surgeon H. B. Parker, relieved from special temporary duty at Vera Cruz, Mexico, to date from July 22. Granted leave of absence for seven days from August 19.

Asst.-Surgeon T. B. McClintic, to report to director of the laboratory for duty, to take effect Aug. 1, 1903.

Asst.-Surgeon C. W. Wille, relieved from duty at the laboratory, to take effect August 3. Detailed as inspector of unserviceable property at Baltimore.

A. A. Surgeon J. M. Delgado, granted extension of leave of absence for seven days from August 12.

A. A. Surgeon J. P. C. Foster, granted leave of absence for seven days from August 19.

A. A. Surgeon C. M. Frissell, Department letter of Aug. 6, 1903, granting him leave of absence from August 6 to 18, amended to read from August 10 to 25.

A. A. Surgeon F. J. Schug, granted leave of absence for ten days from August 15.

A. A. Surgeon A. E. Spohn, granted leave of absence from July 26 for thirty days.

APPOINTMENTS.

Jamin H. Hamilton, appointed acting assistant surgeon for duty at Richford, Vt.

Stacy D. Williamson, appointed acting assistant surgeon for duty at Malone, N. Y.

PROMOTIONS.

Asst.-Surgeons L. D. Fricks, V. G. Heiser and M. J. White commissioned (recess) as passed assistant surgeons, to rank as such from Aug. 2, 3 and 4, respectively, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the weeks ended Aug. 22 and 20, 1903:

SMALLPOX—UNITED STATES.

California: Los Angeles, Aug. 8-15, 1 case; Sacramento, Aug. 1-8, 1 case; San Francisco, Aug. 2-16, 3 cases.
Colorado: Denver, July 11-25, 10 cases.
Illinois: Belleville, Aug. 15-22, 1 case; Chicago, Aug. 1-8, 15-22, 28 cases, 2 deaths.
Louisiana: New Orleans, Aug. 15-22, 1 case, imported.
Massachusetts: Fall River, Aug. 8-22, 9 cases; Taunton, Aug. 1-8, 15-22, 5 cases.
Michigan: Detroit, Aug. 8-15, 1 death; Grand Rapids, Aug. 15-22, 1 case; Port Huron, Aug. 8-22, 3 cases.
Minnesota: Minneapolis, July 27-Aug. 3, 1 case; in 7 counties at 11 localities, 29 cases, 1 death.
Missouri: St. Louis, Aug. 15-22, 4 cases.
Nebraska: Omaha, Aug. 8-15, 2 cases.
New Jersey: Hudson County, Aug. 16-23, 1 case.
Ohio: Cleveland, Aug. 8-15, 1 case; Dayton, Aug. 8-22, 3 cases; Hamilton, July 11-18, 1 case, should have been reported July 6; Toledo, Aug. 8-15, 1 case.
Pennsylvania: Allegheny, Aug. 10-17, 2 cases; Pittsburg, July 25-Aug. 15, 135 cases, 31 deaths, 1 case imported; Scranton, Aug. 8-15, 1 case.
West Virginia: Wheeling, June 1-30, 9 cases, 3 deaths.
Wisconsin: Milwaukee, Aug. 1-8, 3 cases.

SMALLPOX—FOREIGN.

Austria: Prague, July 18-Aug. 8, 8 cases.
Belgium: Antwerp, July 26-Aug. 8, 5 cases, 2 deaths; Brussels, July 26-Aug. 8, 3 deaths.
Brazil: Rio de Janeiro, July 12-26, 13 deaths.
Chile: Amtofogasta, June 1-30, 5 cases, 3 deaths.
China: Shanghai, July 7-14, 1 case, 1 death.
Colombia: Bocas del Toro, July 28-Aug. 4, 1 death.
Germany: Bremen, July 26-Aug. 1, 1 case, 1 death, emigrant.
Great Britain: Birmingham, July 26-Aug. 8, 3 cases, 1 death; Dublin, July 26-Aug. 15, 1 case, 1 death; Dundee, July 18-Aug. 8, 4 cases; Leeds, July 26-Aug. 8, 11 cases, 3 deaths; Liverpool, Aug. 1-15, 13 cases, 3 deaths; London, July 26-Aug. 8, 4 cases; Manchester, July 26-Aug. 8, 4 cases, 1 death; Newcastle-on-Tyne, July 19-Aug. 8, 13 cases, 3 deaths; Nottingham, July 25-Aug. 1, 6 cases; Sheffield, July 26-Aug. 8, 3 cases.
India: Bombay, July 1-28, 24 deaths; Calcutta, July 11-18, 2 deaths.
Mexico: City of Mexico, July 18-Aug. 16, 36 cases, 17 deaths; Hermosillo, Aug. 11, epidemic; Magdalena, Aug. 11, epidemic; Tegucigalpa, Aug. 15, present.
Russia: Moscow, July 18-Aug. 1, 4 cases, 2 deaths; Odessa, July 26-Aug. 1, 1 case; St. Petersburg, July 18-Aug. 1, 10 cases, 2 deaths; Warsaw, June 20-July 18, 8 deaths.
Turkey: Smyrna, June 21-July 19, 16 deaths.

SMALLPOX—INSULAR.

Philippine Islands: Manila, June 13-July 11, 9 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, July 12-26, 4 deaths.
Colombia: Panama, Aug. 3-17, 6 cases, 2 deaths.
Costa Rica: Limon, July 30-Aug. 13, 3 cases, 4 deaths.
Ecuador: Guayaquil, July 18-25, 1 death, sporadic.
Mexico: City of Mexico, Aug. 8-16, 1 case, 1 death; Linares, Aug. 26, epidemic; Merida, Aug. 1-12, 10 cases, 5 deaths; Tampico, Aug. 8-15, 14 cases; Vera Cruz, Aug. 8-15, 53 cases, 15 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, June 20-July 11, 21 cases, 17 deaths; Provinces, June 20-July 11, 1,486 cases, 1,003 deaths.

CHOLERA—FOREIGN.

China: Hongkong, July 8-15, 1 death.
India: Bombay, July 14-28, 2 deaths; Calcutta, July 11-25, 39 deaths.
Straits Settlements: Singapore, June 20-July 4, 3 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, June 13-July 11, 19 deaths.

PLAGUE—FOREIGN.

Africa: Cape Colony, June 20-27, 5 cases.
Brazil: Rio de Janeiro, July 12-26, 2 deaths.
Egypt: General, July 11-18, 27 cases, 9 deaths.
China: Amoy, June 11-18, 840 deaths, estimated; Funchau, July 8-15, becoming epidemic; Hongkong, July 8-27, 87 cases, 64 deaths.
India: Bombay, July 14-28, 143 deaths; Calcutta, July 11-25, 17 cases; Karachi, July 12-26, 2 cases, 1 death.
Mexico: Bagio, Aug. 17, 3 cases; Sequeros, Aug. 18, 3 cases.

THE SUBCUTANEOUS INJECTION OF PARAFFIN FOR THE CORRECTION OF DEFORMITIES OF THE NOSE.*

F. GREGORY CONNELL, M.D.

SURGEON TO ST. VINCENT'S HOSPITAL.

LEADVILLE, COLO.

The surgical use of paraffin as a prosthetic measure is a recent advancement in the surgical art and consequently is in a more or less experimental stage of development. The first instance in which it was used in an attempt to remedy a defect in the human anatomy dates back but a few years, and while the number of cases in the literature is increasing rapidly, they are still so few in number that every operation of this character should be reported. It is only by a careful classification and study of a large number of cases that we may be enabled to arrive at a definite conclusion as to the merits and demerits of the method, as a recognized surgical procedure.

The attempts at improvement which terminate unsatisfactorily are of even more import than are the cases which result favorably. The temptation is to report the successful operations and to postpone indefinitely a report of those cases which had an unfavorable outcome, in this way giving to the one searching for a verdict on the method, a biased conception as to the results one may reasonably anticipate.

The satisfactory results are sufficient evidence in themselves. The failures demand further attention and investigation both from the operator and the profession at large, in an attempt to discover the cause of the fault, and to place it at the door of the method, or of the one who employs the method.

The report of disastrous results should not be confined to the lay press but should appear at length in the medical press, and in this way tend toward the prevention of a repetition of the failure. Not long ago the daily papers, through a press dispatch from Paris, called attention to the case of a young girl who, not satisfied with the appearance of her nose, submitted to an operation in which paraffin was injected subcutaneously to replace a defect, as a result necrosis ensued and the loss of the entire nasal organ was threatened.

Cases such as this demand the most careful scrutiny on the part of the profession before an attempt at a decision as to the value of the new method can be made, and these cases should be brought to the attention of the profession by the one who had the case in charge.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

THE ORIGIN OF THE METHOD.

The subcutaneous injection of oils and liquid paraffin dates back almost to the origin of the hypodermic needle and syringe; especially has it been used in the treatment of syphilis, as a vehicle for the suspension of insoluble medicaments. Corning in 1891 presented an article entitled, "Localization of Remedies About the Sensory Nerves of the Skin," in which we find the first use of a solidifying oil in surgery. As the title implies, the object of this method was to fix medicament, usually an analgesic, in a particular neighborhood by the injection of the oil immediately after, and through the same needle, and then by a cold application, or the refrigerant spray, the oil was solidified, and the absorption or dissemination of the drug prevented.

In 1894 Corning enlarged the application of this subcutaneous injection of paraffin, by its injection into a muscle for the arrest of spasm. This was accomplished with a satisfactory result and the name "Eleomyenchysis" applied to the procedure. The same investigator, in 1896, utilized this substance in still another manner. After the subcutaneous division of a nerve for neuralgia, paraffin was inserted between the two divided ends, and then solidified by the external application of cold. Regeneration of the nerve ends and the return of pain were in this manner prevented.

The *Medical Record,* in an editorial on this phase of the subject, concludes as follows: "It is clear that the credit for the idea of the mechanical employment of oils in the tissues belongs wholly to Dr. Corning. And not only is he entitled to the honor of originating the principle, but also to credit for developing a method far more scientific than that of any of his followers."

From a survey of the available literature, it would seem positively proven that, as quoted above, the principle of the subcutaneous injection of paraffin was first utilized by Corning, but also that Gersuny in his article of 1900 entitled, "Ueber eine Subcutane Prosthese," was undoubtedly the first to recommend the use of, and to use, paraffin, subcutaneously, as a prosthetic measure.

The fact that paraffin or vaselin can be sterilized, made to melt at a given temperature, and when injected under the skin, will give rise to no untoward symptoms, no toxic absorption, no marked inflammatory reaction, and no pain or discomfort, but instead serve as a non-irritating framework which acts as a support of newly formed connective tissue—these facts form the basis, the foundation of all that has been done with paraffin as a prosthetic substance during the past few years, and it would seem that this was first brought out by Corning of New York, and then re-emphasized and enlarged by Gersuny of Vienna, so much so that the procedure is commonly known as "Gersuny's Method."

The writings of Gersuny and his assistants have led surgeons throughout the land to utilize this substance

in efforts to repair, or improve on, defects in the human anatomy. These defects have been of a great variety and include almost every possible sort of deficiency, defect or blemish which human flesh and bone is heir to. The first instance in which it was used in the human body was for the formation of artificial testicles in a person who had been castrated for tuberculosis of those organs. This was successfully accomplished by Gersuny in 1899, and at the last report, after the elapse of over three years, the artificial testicles were in perfect condition, and, to the palpating fingers, felt like cartilaginous masses. This, notwithstanding the fact that the patient had passed through a severe attack of typhoid fever, his temperature rising to 40 C. (104 F.). At the time of this high temperature, the masses of paraffin within the scrotum were noted as becoming a little softer, but after the decline of the temperature, they returned to their former consistency.

FIELD OF EMPLOYMENT.

Among the other conditions in which this method has been employed might be mentioned inguinal and umbilical hernia, incontinence of urine, incontinence of feces, prolapse of rectum, prolapsus ani of children, prolapse of uterus, displacement of uterus, cleft palate, partial and complete, prevention of post-operative adhesions, obliteration of scars resulting from accident, obliteration of scars resulting from mastoid or frontal sinus operation, obliteration of scars resulting from confluent smallpox, to restore the symmetry of the face in facial hemiatrophy, to restore the symmetry of the face after the removal of maxillæ, as a foundation for an artificial eye, to repair the defect after resection of the ribs, to prevent ankylosis of joints after resection, to prevent regeneration of nerves after resection and the formation of artificial turbinated bones.

The above are among the more usual indications for the employment of this method; while the most frequent defects for which the subcutaneous injection of paraffin has been resorted to, if one may judge from the literature, are deformities of the nose.

It would also seem, from the literature, that in but one deformity of the nose has repair been attempted by this procedure. That is the "saddle-back" nose. This may be, and in all probability is because it is by far the most common deformity of the nose, in which there exists a defect which may be filled in. Of course in that variety of malformation in which there is an increase of tissue, this method will, as a general proposition, be contraindicated.

CLASSIFICATION OF NASAL DEFORMITIES.

Roe has classified nasal deformities as follows:

Deformities of the nose	Bony portion..	Vertical...	Convex.
			Concave.
		Lateral...	Spatulated.
			Deflected.
	Cartilaginous portion.	Tip.....	Excessive or deficient tissue
			Deviation from median line.
		Wings...	Collapsed.
			Expanded.

From this classification, it will be seen that in a fair proportion of the various deformities it is both practical and possible to remedy the defect by the subcutaneous injection of paraffin; and not only remedy the defect, but in addition, do so in a manner much better and more rapidly, and with considerable less inconvenience, to both operator and patient, than by means of any other known method at our disposal for the remedy or improvement of such condition.

The most satisfactory results, the extreme simplicity of the procedure, and the rapidity with which the irregularity is corrected are all more pronounced when compared or contrasted with the more unsatisfactory, complicated, and time-consuming (both to the patient and the operator) methods previously advocated, such as the so-called plastic operations, and in the methods which include the insertion of a foreign substance such as metal, celluloid, or ivory plates or strips.

Of those deformities included in Roe's classifications, the concave vertical or the saddle-back nose is beyond all doubt the condition *par excellence* for the employment of this procedure.

Among the other deformities of the bony portion of the nose, this line of treatment is not at all constantly indicated, but cases might arise in which the spatulated or deflected lateral variety of nasal deformity could be made less noticeable, by the use of this foreign body inserted subcutaneously. In the convex vertical, where there is a redundancy of tissue, there seems to be practically no indication for its use.

As to the cartilaginous portion, when the tip is deficient in size, this method will be again found to be available in improving the appearance of the organ. When of excessive size, and when deviated from the median line, there is little, if anything, to be gained by using the method under discussion. When the wings are collapsed we have found the method satisfactory in causing the alæ to resume their relatively normal position and appearance. And with the wings expanded, it is again found to be of no practical value. This review of the possibilities of the procedure will show a very wide field for its usefulness, and serve as a satisfactory excuse for its serious consideration.

INDICATIONS.

On account of the character of the work involved, the method must be proven to be absolutely harmless, devoid of any possible danger when properly applied, before it should or can become a recognized surgical procedure. The operations in which this method will be employed are not, as a rule, matters of necessity, and when performed, in an attempt to remedy a slight defect in a person's countenance, a defect often exaggerated in the mind of the patient applying for improvement, one must be reasonably, if not absolutely, certain that this defect will not be, by any chance, made worse than it was originally. Very frequently the irregularity of the face is such that, to an uninterested person, it would seem that the deformity had better be left alone.

The fact that a patient comes to you to have his or her appearance improved on, is certain evidence, or at least satisfactory evidence, in the vast majority of instances, that he or she is hypersensitive about the matter, and is more than likely to be dissatisfied with the result of your attempted improvement, even though it be satisfactory from a surgical view point. Such cases differ and should be differentiated from those in which the nature of the defect demands that some measure, operative or otherwise, be taken in order to prevent that person from becoming an object of either pity or ridicule throughout the remainder of his days, if no attempt at improvement is undertaken. In such cases it is always justifiable to make an attempt at improvement of the existing conditions. In another class of cases, those in which the deformity is comparatively trifling, in many instances it is not indicated nor justifiable to operate on them.

THE DIFFICULTIES.

The possible causes of failure, in the latter class of cases especially, should always be most fully and care-

fully presented to the patient, and then it is for him to decide whether or not to undertake the risks, as there is always a risk associated with the performance of an operation of this character.

These possible sources of failure, and therefore objections to the method, many of them chimerical, some theoretical, and others real and existing, may be enumerated as follows:

1. Toxic absorption.
2. Marked inflammatory reaction.
3. Loss of tissue, due to infection and abscess formation.
4. Pressure necrosis, caused by the injection of too much paraffin.
5. Sloughing of tissue, as a result of the heat of the paraffin.
6. Injection into very dense, or inelastic structures, or where scar tissue is firmly attached to the underlying and adjacent parts.
7. Injection of too small an amount of paraffin, with an insufficient correction of the deformity.
8. Injection of too large an amount of paraffin, with an overcorrection of the original deformity.
9. Air embolism.
10. Paraffin embolism.
11. Extension of the paraffin, when first introduced, into adjacent normal structures, such as the infraorbital region.
12. Interference with the muscular action of the nose.
13. Escape of the liquid paraffin, after the withdrawal of the needle.
14. Solidification of the paraffin in the needle, which renders the injection difficult, and causes injudicious expedition on the part of the operator.
15. Absorption or disintegration of the paraffin.
16. The difficulty of procuring paraffin with the proper melting point.
17. A resultant hypersensitiveness of the skin over the injected area.
18. A marked and more or less permanent redness of the skin over the injected area.

These, the more important objections, will be taken up seriatim and considered more or less at length, as may be required in each instance.

INTOXICATION.

1. The danger of an intoxication due to the absorption of paraffin was one of the first objections raised against the method; but it is now generally conceded that when such symptoms occur they are due to some impurity of the substance injected. Meyer was the first to emphasize this objectionable point, and his position was corroborated by the animal experiments of Straume, Dunbar, Stubenrath, and Sobieranski. These men injected paraffin in the lower animals, and for some reason procured a decided constitutional reaction, which they attributed to the toxic qualities of the foreign substance.

On the other hand, the experiments of Stein and of Smith demonstrate that this injection may be, and in their experience was, followed by no reaction, either constitutional or local. Jukuff made similar experiments, and concludes that the amount of paraffin injected subcutaneously, necessary to produce toxic symptoms, must be equivalent to 10 per cent. of the body weight of the animal into which it is injected. Granting the accuracy of his experiments, it would place the dangerous amount in the neighborhood of from ten to fifteen pounds, a quantity greatly in excess of the maximum dose employed in prosthetic surgery. These latter experiments, with the more convincing and constantly increasing number of satisfactory cases on the human being, have led to the belief that the experiments first cited were imperfect in some respect, either in an impurity of the injected substance or some error in the technic employed, and that there is no danger of any toxic absorption in the method.

REACTION.

2. A mild transitory inflammatory reaction usually occurs after the injection. A marked inflammatory reaction has been noted in but very few of the reported cases, and in these was usually due to avoidable and extraneous causes. The mild reaction that does take place before the encapsulation occurs is seldom of sufficient severity to warrant its being classed as inflammation.

INFECTION AND NECROSIS.

3. Infection followed by abscess formation, and, in consequence, a loss of tissue, can not be reasonably held against the method, but rather against the technic used in employing the method. This danger, infection, is no greater after this procedure than following the ordinary usage of the hypodermic syringe, which in proper and competent hands is practically *nil*.

4. The pressure necrosis that may be caused by the introduction of too large an amount of paraffin, is one of the most dangerous, humiliating and aggravating outcomes that may follow the use of this method, and it undoubtedly has occurred in a certain proportion of the cases. With the surgeon carefully molding the mass with the fingers of the left hand, as the paraffin is being introduced, in this manner being all of the time cognizant of the amount of pressure that is being exerted on the overlying skin, such an accident should rarely, if ever, occur. The circulation should always be perfect over the injected mass immediately after the conclusion of the operation. This can readily be determined by noting the return of the blood to this area after a local ischemia has been produced by digital pressure.

5. Sloughing of the skin has been noticed in cases where the harder paraffins have been used—those with a high melting point (59 to 65 C., 136 to 149 F). This is one of the objections raised to the use of the harder paraffins by those who employ that with a lower melting point. It is not rational to presume that such an occurrence would take place after the injection of paraffin with a melting point of 110 F.

6. In cases where the tissue covering the defect is very firmly attached to the underlying structures, and when it is necessary to inject into a very dense and inelastic tissue, the danger of sloughing is considerably greater. In order to reduce this danger, under the first circumstance it is advisable to detach the cicatricial tissue in some manner, before the injection, preferably by means of a subcutaneous incision. In the latter instance, it has been recommended that the injection of the paraffin be preceded by the injection of Schleich's solution into the area that the paraffin is to occupy. This would serve the double purpose of anesthetization and of dilating the tissue in preparation for the paraffin soon to follow.

Injection into this class of tissues was not originally intended, and is not to be enthusiastically recommended, even though a number of instances in which it has been successfully carried out have been reported.

ERRORS OF TECHNIC.

7 and 8. The introduction of too large or too small an amount of the substance is an error of technic and within the control of the operator. The latter is a comparatively slight fault, if one at all, and can be easily remedied by a subsequent injection. It is, indeed, a preferable manner of dealing with these conditions. It has been recommended that we make numerous injections of

a small amount each time, instead of attempting to remedy the entire defect at a single sitting. In this way one obviates the danger of making too large an injection. Freeman has noted a confusing amount of edema occurring very rapidly, which makes it sometimes difficult to accurately estimate the amount of paraffin needed; at a second step of the operation the further requirements can be more accurately determined. Other advantages of this operating in stages are that, at the second sitting, there exists a more substantial basis to work on, i. e., the previously injected material. The skin is given an opportunity to gradually stretch and accommodate itself to the new state of affairs without any undue or hazardous tension.

The introduction of too large an amount of paraffin is an extremely difficult matter to remedy, hence great care should be exercised in attempting to prevent such an occurrence. The best treatment of this condition is prophylactic, i. e., as cited above, numerous injections of small amounts in preference to single injections intended to remedy the entire fault. Paraffin, while soluble in a number of substances, such as ether, chloroform, xylol, benzine, etc., can not be acted on by these through the skin.

Smith reports one case in which it was necessary to remove some of the injected paraffin. He made a subcutaneous opening and endeavored to curette some of it away, but found that it had become so intimately embedded in the tissue that it was impossible to remove it without removing a large amount of newly formed connective tissue as well.

EMBOLISM.

9. Air embolism is a very slight danger in all cases in which a subcutaneous injection is made, but can be readily excluded by taking the precaution to expel all the air in the needle and syringe before introducing the needle beneath the skin—the same as is done every day before hypodermic injections are made, i. e., hold the syringe erect, allow the air to come to the top, and then press on the piston till the air is forced out and the fluid escapes at the tip of the needle. But that this danger of air embolism is greatly exaggerated can be readily seen by referring to the experimental works of Senn and of Hare and also by the absence of symptoms of air embolism, after hasty and careless subcutaneous injections.

10. The introduction of paraffin into a vein, either directly or indirectly, and lung embolism as a result, is one of the most serious and consistent of the objections which have been raised against this line of treatment. Consistent, in that such cases have been reported by Pfannenstiel, Leiser and others, showing that the objection is not without foundation in fact. It is a fault which bears with equal force in any method of subcutaneous injection of a solid, semisolid or liquid, insoluble substance.

In Pfannenstiel's case, in which there was injected 30 c.c. of paraffin at the melting point of 45 C. (113 F.), the injection was followed by the typical symptoms of embolism, as described by the syphilographers, that has followed the injection of mercurials in oil, such as cough, chill, headache, vomiting, increased respiration and later dyspnea and cyanosis. The symptoms are usually very mild, death very rarely, if ever, occurring from this cause alone. In Pfannenstiel's case, the symptoms persisted for about one week and then gradually subsided with recovery of the patient.

Attention has been called, in this connection, to the experience of the dermatologists, with embolism after the injection of mercurial preparations suspended in liquid oils or paraffins. And from a review of the literature on that subject it would seem that embolism is far more likely to follow the parenchymatous than the subcutaneous injection, but in neither is it absolutely excluded, but apparently present in a small percentage of all the cases so treated.

This radical difference is to be noted between the injection of the liquid oil, as is done in treating syphilis, and the method under consideration. In the former the substance is in a fluid state, therefore absorption and emboli are more likely to occur than in the latter, where the injected substance is semisolid. With the injection of paraffin that emerges from the needle, as a worm-like string, and not in a fluid state, it seems that the danger of embolism may be very materially diminished, if not excluded. Comstock says: "In all cases in which paraffin was used at 102 F. the animals died within two weeks' time, hence the specimens at that temperature are limited (death being caused by thrombosis). . . . In all other cases, with the higher melting point, 110 F., no unpleasant results were experienced whatever."

Explanations of the accident in Pfannenstiel's case have been offered, such as: The temperature of the paraffin was too high, consequently it was injected hot and liquid, thus favoring absorption; or, the high temperature caused a coagulation of the blood in the veins, in this manner favoring the occurrence of thrombosis and embolism. Again, it has been said that so large an amount of paraffin, at so low a temperature, could not possibly harden when under the skin for some little time after the operation, and in this way make possible the occurrence of absorption and embolism. Other explanations are: That the injection was made parenchymatously instead of subcutaneously; that the injection might have been made directly into a vein.

For the prevention of embolism, it has been recommended that the injection be made into the subcutaneous tissue only and never into the parenchyma and that paraffin be utilized that has a melting point neither too high nor too low, this being best determined by seeing that the paraffin emerges from the needle, at the room temperature, in a worm-like string.

Stein says that all that is necessary to avoid pulmonary embolism is to avoid the pricking of a vein, and recommends that only subcutaneous injections be made, and that the needle be first inserted, and only after it has been demonstrated that no blood flows through it, should the syringe be attached.

Freeman says: "This danger may, perhaps, be avoided by using a blunt-pointed needle, after having first punctured the skin with a sharp one."

Paget advocates the application of a firm and close pressure all around the nose during the injection. Jukuff of Strausburg found unfavorable or fatal results experimentally, after the injection of over one-tenth of the body weight of the animal, or when the injected paraffin had a melting point below the temperature of the body. In the later instance, the autopsy invariably disclosed thrombosis in many of the smaller veins, and embolism of the lungs. Comstock concludes that paraffin must be used where it will be at all times above the temperature of the body, in order to prevent any danger from embolism.

UNDUE SPREADING OF THE PARAFFIN.

11. The paraffin, when first introduced under the skin, may extend to regions of the face that are normal, and not in need of this artificial substance. Such an exten-

sion to the loose areolar tissue of the infraorbital regions while injecting for the repair of a saddle-back nose is not uncommon. Such accidents are due to a hyperinjection, and care should be exercised, and only a proper amount of paraffin introduced.

Firm digital pressure around the nose, made by an assistant, may prevent such an occurrence. Paget states that this firm digital pressure may be helped by the use of a strip of lead or pewter beneath the fingers. Downie recommends the use of celloidin, as follows: Fifteen minutes before the injection he paints a band of celloidin (collodion will answer the same purpose) across the nose at the level of the eyes, and down each side of the nose, at the junction with the cheeks; this contracts and helps to prevent the paraffin from passing into the cellular tissue beneath the eyes. Immobility of the parts, and the local application of ice or cold, have been advocated as aiding in the more rapid setting of the mass, and in this way preventing its extravasation into undesirable parts.

12. Alter has called attention to a paralysis of the muscular action of the wings of the nose, resulting in impeded nasal respiration. He states that the current of air rushing into and through the nose carries with it an inherent tendency to draw the alæ septalward; this, however, in normal conditions is counteracted by the action of the dilators of the alæ nasi, viz., dilator naris posterior, dilator naris anterior, pyramidalis nasi, and the levator labii superioris alæque nasi. The modus operandi of this interference with the action of these muscles, according to Alter, is by compression, the presence of the paraffin interfering mechanically with their free muscular action, resulting in collapse or inward drawing of the wings of the nose during inspiration. He cites one case in which this interference with inspiration was very marked, after the injection of the paraffin.

As a preventive measure against such an occurrence, he recommends that an assistant make firm pressure on the wings of the nose, by placing a thumb in each nostril, and the making of counter-pressure on the outside with the index finger, this pressure being maintained until the nose has been molded into its proper shape.

13. There is but little danger that any of the paraffin will escape between the time of the withdrawal of the needle and the sealing of the wound puncture with collodion, if it is injected while in a semisolid state, as it should be. But it has been suggested that a piece of gauze soaked in ice water be placed over the nose before the withdrawal of the needle, and so hasten the setting of the paraffin and preventing its escape at the time of the withdrawal of the needle.

THE SYRINGE TO BE EMPLOYED.

14. Another annoying feature is the setting or the solidification of the paraffin in the needle before the injection is made, necessitating undue haste in the operation or great difficulty and force in the injection. To obviate this it has been recommended that the syringe be kept in a receptacle of hot water after being filled and until ready for use; or, a fine wire, such as is to be found in hypodermic cases, may be inserted into the needle to remove the obstruction. Downie winds the outside of the needle with a fine platinum wire, which is then kept hot by being connected with a storage battery. Eckstein places a rubber tubing over the syringe to keep in the heat. Karewski of Berlin has invented a syringe for this purpose, surrounded by a jacket through which circulates a continuous current of hot water.

In the writer's opinion, the best method to prevent this aggravating delay in the technic is by the employment of a syringe similar to the one described by Smith, and also used by Leonard Freeman, i. e., one in which the piston rod is surrounded by a coarse screw worm, and fitted on this rod is a metal thumb screw, which runs up and down, and is made to screw into the upper end of the cylinder of the syringe, at the volition of the operator. When the thumb screw is not fitted into the cylinder the piston works up and down, as in an ordinary syringe, and any liquid can be drawn up and expelled readily by manipulation of the piston; but when the thumb screw is put into place it becomes necessary to screw the piston down, and by so doing the paraffin is slowly and evenly ejected from the needle. By using a syringe of this character the necessity of an embarrassing haste and of a force, hard to apply, is dispensed with.

Before becoming familiar with the construction of such a special syringe the writer had improvised one by using the ordinary syringe with a screw worm on the piston rod, and on this screw a plate, which can be made to run up and down the piston rod. By a simple mechanism this nut or plate was fixed in place at the top of the cylinder of the syringe so that it could not turn. By screwing the piston rod we arrived at the same result as is achieved by the special syringe; that is, a uniform and steady pressure, with an equal and even advance of the paraffin, resulting in a regular and continuous, smooth emptying of the barrel of the syringe.

ABSORPTION OF THE PARAFFIN.

15. The point has been raised that the paraffin will serve as a temporary support only and soon disappear; that it will become absorbed or disintegrated. According to Gersuny, the mass of paraffin is not taken up by the lymphatics, but remains as an inert non-irritating body which soon becomes encapsulated and is subdivided by an ingrowth of newly formed connective tissue; the mass of paraffin finally becomes very finely divided and partially emulsified. These finely divided particles of the substance are first seen at the periphery of the mass and finally are absorbed, their place being by this time taken by new connective tissue, which gradually becomes harder, until it closely approaches the consistency of cartilage. This same chain of events has been noted, experimentally, by Juckuff.

This theory as to the ultimate destiny of the paraffin seems to be corroborated, and to coincide with the facts, in Smith's case, in which he endeavored to remove some part of the injected paraffin a number of months after the injection, and found that the greater part of it had become so intimately embedded in the meshes of the newly-formed connective tissue that it was almost impossible to remove the paraffin without also removing considerable of the connective tissue. Regarding this question, Stein believes that it is reabsorbed little by little, and replaced by connective tissue, so that the persistency of the plastic result is assured. And what confirms him in this opinion is that, whatever be the melting point of the paraffin—and it may vary considerably—the consistency of the nodule augments or diminishes by degrees, according to the case, so that at the end of a month or so, it is always perceptibly analogous to cartilage.

Freeman says encapsulation soon takes place, just as it does with a bullet or any other foreign body. A limited amount of connective tissue also penetrates the material, which is speedily converted into a solid cartilage-like mass.

Kramer has used melted agar-agar in subcutaneous injection for the production of connective tissue artifi-

cially, and has made interesting experiments on animals. On microscopic examination of the substance at different times he finds that the mass of agar at first becomes infiltrated with round cells, and that then these are replaced by vascularized connective tissue.

Comstock presents a most thorough and valuable work on the injection of paraffin, experimentally. He has made a most comprehensive study of the histologic and pathologic changes in the tissues of the body, and of the changes in the substance itself, after varying lengths of time and after the utilization of paraffins having different melting points. His conclusion is as follows: "In paraffin we have a substance that will fill in spaces of lost tissue, and not remain entirely a capsulated foreign body, but become a bridge work and, in fact, a part of the new tissue."

Downie injected some paraffin into a female breast one week prior to the amputation of that structure for malignant disease. After the removal of the breast, sections were made and examined. The paraffin was found in masses of various size located between collections of adipose vesicles, which were displaced by them. He infers that the paraffin had made its way along the lines of connective tissue trabeculæ, between the fat-containing cells. It is difficult for him to believe that the position of the paraffin would subsequently alter, to any extent, although its absorption seems quite possible.

Gersuny's first case was performed in May, 1899, and in the last report of that case, after a lapse of three years, there was noticeable no diminution in the size of the prosthesis.

This, with the other cases and experiments, would seem to indicate that if the paraffin is absorbed it is replaced by connective tissue, or if absorbed and not replaced by new tissue, it is absorbed so very slowly as to have no practical bearing on the advisability of operating by this method.

Granting that the prosthesis will gradually become smaller in time, from absorption or any other cause, repeated injections may be made at intervals, as the case may require, with but a small part of the inconvenience to the patient, as that which would accompany any of the so-called plastic operations in vogue before the introduction of the injection method, or, in the majority of cases, with less discomfort than will be associated with the persistency of the original deformity.

PREPARATION OF THE PARAFFIN.

16. To obtain a paraffin that has the proper melting point is something of a time-consuming and tedious procedure. The ordinary soft paraffin has a melting point of about 120 F., and this must be mixed with the white cosmolin, or vaselin, of commerce, which melts at about 100 F. The mixture is heated and its melting point determined by the following procedure, as recommended by Gersuny: The bulb of a clinical thermometer is coated with the mixed paraffins, and placed in a water bath, which is slowly heated until the paraffin melts and floats on the surface of the water; the heat is then removed, and the temperature of the cooling water noted, when the transparent drops of paraffin become opaque once more. If this temperature is not the desired one, the process must be repeated, after a recombination of the two paraffins, with the addition of more soft, if the melting point is too high, or the addition of more hard, if it is too low.

This tedious and objectionable experimenting in order to procure the proper mixture of paraffins has been rendered unnecessary by Dr. Harmon Smith of New York, who has had a paraffin prepared with the proper melting point in sterile sealed test tubes, and for sale in the market. It is advisable, as a regular procedure, to resterilize this commercial article by heating before using it. The paraffin prepared by Smith has a melting point of 110 F.

This brings us to a discussion of the question as to the proper melting point of paraffin intended for subcutaneous injection. Here we find considerable variance of opinion. Moszkowicz, Gersuny's assistant, states that the paraffin must have a melting point between 36 and 40 C. (97-104 F.). In speaking of Pfannenstiel's case, Moszkowicz said: "He injected paraffin with a melting point of 45 C., which is much too high." Parker utilized a paraffin with a melting point of 102 F. Leonard Freeman uses a paraffin that melts in the neighborhood of 40 C., 104 F. In Downie's cases the melting point varied from 104 to 108 F. Paget at first used a paraffin that melted at 136 F., then later one that melts at 115 F., and still later a mixture that melts at 111 F.

In the vast majority of the instances in which the method has been employed, the melting point has been in the neighborhood of 110 F. A higher melting point has been recommended and advocated strenuously by Eckstein, Karewski and others, the former placing the best point of liquidation between 56 and 58 C. (133 to 136 F.), and the other saying that the melting point should not be below 57 or 60 C. (134 to 140 F.). Paget says: "I am absolutely sure now that Eckstein's paraffin is without any real advantage. It is very difficult to handle, it sets very rapidly, it causes a gread deal of swelling and some inflammation, and may even produce some discoloration of the skin, and it yields no better results then does Pfannenstiel's paraffin, which melts at 115 F."

Comstock, after experimenting on animals with this point in view, says: "Paraffin must be used where it will be at all time above the body temperature." He also says: "In selecting the melting temperature point for surgical uses, allowance will have to be made for the difference in temperature between the rabbit and human species, which is about 4 F., making a choice of 106 or 107 F., the best for use in subcutaneous injections, for the reason that it gives a substance firm enough to hold very well its form, especially when confined by the surrounding tissue, and at the same time with a melting point out of the reach of the system at all times."

Some of the objections entered against the use of the harder paraffins are: Difficulty in manipulation at the time of the operation; heat and hardness, which are liable to favor the occurrence of irritation, inflammation or even necrosis; its liquid state at the time of the injection, which makes its localization more difficult and uncertain and which makes the formation of emboli possible. Paget calls attention to the fact that when the paraffin "sets" it shrinks, and the harder the paraffin the greater the shrinkage. Those preferring the use of the harder paraffin reply by stating that the softer mixtures, because of the longer time required for them to set, are more liable to extravasate, are less durable and permanent, and are more liable to form emboli.

Disregarding these theoretical points, from the literature, one must be convinced that the melting point most generally used is one between 105 and 115 F., though satisfactory results are not lacking in which paraffins of a higher melting point have been used.

SENSITIVENESS AND REDNESS OF THE SKIN.

17. A resultant hypersensitiveness of the skin over the injected area is a theoretical objection that has been

raised against this method of treatment, but which has not materialized in any of the available reported cases. There has been, in many cases, a slight painfulness, or rather a sense of fulness or distension, for a short time after the operation, and in some few cases a more marked painfulness existed for a longer time, but this invariably soon passes away and the sensation remains perfectly normal in every respect.

18. A redness of the skin over the injected area has been noted by many operators, but it has always been transitory in the reports of cases that have come under the writer's observation. Paget says: "In a few cases —but only in a few—some reddening of the skin has followed the injection, and in a very few this has been very slow to fade." These few cases occurred in a series of twenty-two cases, and we are not told whether it occurred more frequently after the injection of the paraffin with the high or the low melting point.

In one of the six injections reported with this small contribution to the subject, it will be found that this redness resulted and has been present for over a year, and during that time has diminished very little.

This resulting redness of the skin is the only objection of the many sources of failure or objections herein cited that I have found existent in my very limited experience.

(The conclusion of this article will appear next week with an article on the same subject by Dr. Harmon Smith.)

PRECISION IN THE DETERMINATION OF HUMAN PARASITES.*

HENRY B. WARD, PH.D.
LINCOLN, NEB.

The ectoparasites of man are, generally speaking, well known, and many of them have been recognized from the earliest times. They are also easily determined, in the main, while, on the other hand, the difficulties to which they give rise are not, as a rule, serious, but yield readily to simple treatment. With the endoparasites, however, the case is precisely the reverse. They are not, as a rule, more than superficially known, and it is only recently that attention has been generally called to their number and the effects often serious which they produce in the human organism.

To be sure, a long series of such forms has been recorded in the past, and the serious effects of their parasitism has been emphasized in some quarters. Thirty years ago Leuckart[1] listed thirty-three species which had been found in man, and, in company with Virchow and a long list of other investigators, called repeated attention to the delcterious effect certain species exert. Braun's more recent work[2] discusses of certain and doubtful species 15 *Trematoda,* 20 *Cestoda* and 38 *Nematoda,* besides 30 to 40 *Protozoa,* which have been recorded from the human host. In studies on the various groups which I have recently published[3] this list is increased by two species, although the interval between the publication of Braun's lists and mine is not a year.

The various studies, however, have chiefly been made on forms found in the old world. Within very recent times these studies have begun to be extended over other lands. All the new forms recorded during the last five years have been extra-European, either new species peculiar to other lands, or new regions within which known forms have been found to exist. Perhaps the greatest advance has been in knowledge of the geographical distribution of human parasites. The large number of isolated cases of the occurrence of certain species has been supplemented by other cases showing more general occurrence or wider distribution, the results of which have been to demonstrate that these parasites are far more common and widely distributed than was believed heretofore. The accompanying table, which lists all human parasites of the various groups of worms heretofore recorded with a statement of the regions in which they are known to occur, will be of value as indicating the present knowledge on the subject. It has seemed to me best to confine the list to the worms, and to exclude the protozoan parasites for the double reason that the latter are very imperfectly known, and it would be difficult to present a satisfactory list, and, in the second place, that they are also more difficult to determine, even by the professional microscopist, and present insuperable difficulties to the ordinary practitioner.

It may be confessed at the outset that the table is probably incomplete. The individual records are much scattered, and in such form as to demand extensive critical editing. It would be improbable, then, that, even with the great care which has been exercised, all records should have been included. So far as the list concerns Europe and the United States, however, I think it may be said that it is most nearly complete, and includes all but the most obscure records up to the present date. It should nevertheless be borne in mind that one may certainly expect further evidence of the presence of some of these species in unrecorded regions and of the existence of new species in most of the regions of the world. Additional strength is given to this general premise by the discoveries which have been made within the past decade in these United States. Thus Thayer has demonstrated the existence here of the Indo-European *Strongyloides stercoralis.* White has discovered the Asiatic *Opisthorchis sinensis,* I have found the Asiatic lung fluke, *Paragonimus Westermanii,* and a new human tapeworm, *Tænia confusa,* while Stiles, in addition to records on the vinegar eel, *Anguillula aceti,* and other forms new as human parasites here, has contributed the most important of all these studies, namely, that on the widespread occurrence of a new hook-worm, *Uncinaria americana,* which is of great etiologic significance over large areas of our country.[4]

In the belief of the medical profession 200 years ago there was no disease, real or imaginary, which was not due to the presence and effect of some kind of parasite. Each ailment had its particular "worm" in its characteristic location. This was a direct result of the endeavor to reduce every malady to some definite cause, and from a joining of the unknown sickness with the parasites, of which they knew as little. Under the influence of study and of increase of knowledge regarding the parasites, such a theory was seen to be untenable, and the movement in the opposite direction began—a tendency which may be said by this time to have passed its height. In fact, there has prevailed during recent years among the medical men of this country an exaggerated idea of the unimportance of human parasites. It has been very generally maintained that the country was less infested than the old world, or that the

forms, after all, were of little significance in the etiology of disease. I am of the opinion that the discoveries referred to furnish ample grounds for a modification of the position of indifference heretofore assumed, and in the United States, but similar significance has not been accorded to most forms.

Recent studies, however, have demonstrated the presence of hemoglobin in the alimentary canal of many

Explanation of signs.—* Recorded from man; autochthonous to region. † Recorded from man; probably endemic, though often secondarily. ‡ Recorded from man; probably acquired elsewhere. § Recorded from some other host, hence possible in man. ? Record open to question.

in the treatment of disease call for more careful consideration of such forms as possible factors of etiologic significance. The clinical importance of parasites is generally recognized in such cases as bothriocephalus anemia, of which only a very few instances are on record nematode parasites, the pathologic effect of whose activities must be counted much more important than heretofore estimated by reason of this blood-sucking habit. Thus in cases of uncinariasis the amount of blood lost from myriads of minute hemorrhages imparts a char-

acteristic reddish brown color to the feces, the intestinal wall becomes seriously affected, and affords places of easy attack for any pathogenic germs which may be present. This indirect damage may be very serious in the individual instance, and may include primarily or secondarily undesirable regressive or progressive histologic changes, inflammatory processes and disturbances in the circulation.

Another source of danger from parasites is one which has long been surmised, but only recently demonstrated. A number of investigators have shown that various *Cestoda, Acanthocephala* and *Eunematoda* contain definite poisons (toxins) which, when extracted and employed, experimentally, affect particularly the nervous system and the formation of blood. The continued formation and giving off of such a substance would explain the apparently excessive results of parasitism in some instances, results which are shown prominently in reflex nervous symptoms. In a certain proportion of cases, pernicious anemia is the result of this toxic effect, and is accompanied by a mortality of 17 per cent., according to one report regarding *Bothriocephalus.* Whether the poison is elaborated by the parasite, or is produced by pathologic processes in the worm, or by its death, as well as the ground for the variability in the toxic action of different specimens, are questions as yet undecided. It has been shown, however, that the extracts from different species of helminths vary considerably in toxic power. Vaullegeard has isolated two toxic principles, one of which acts on nerve centers and the other on muscles, and many symptoms, produced experimentally by the injection of these substances, are analogous to those manifested in parasitic disease. According to this chemical theory, the troubles caused by parasites are due to the formation of toxic substances more rapidly than their elimination of the host, and their consequent accumulation in the system. A striking instance of the actual effects of parasitism on a large scale is set forth by Stiles[4] in his description of the general anemic condition and the lowered physical and mental vitality of the families and communities where *Uncinaria americana* is common. These considerations are sufficient to show the greater numbers and more serious effects of human parasites in our own country than has been conceded hitherto.

In the next place it is necessary to emphasize the importance of the accurate identification of human parasites. They are by no means all of equal etiologic rank; some are known to exert deleterious effects on the human organism, regarding the action of some much doubt exists, and there are others which are believed to be indifferent to man. Furthermore, even of those whose injurious effects are unquestioned, the results on the hosts differ notably, and the line of successful treatment differs equally. It is evidently important, then, to determine accurately with what species the practitioner has to deal in the individual instance. To-day no one would be satisfied to accept the diagnosis of "fever," and how can the diagnosis of "worms" be regarded as more sufficient?

In reaching a precise determination, the physician has to deal usually with what is purely a microscopic question. The data which are essential are obtainable only by the use of the microscope, and yet they are very easily secured. They do not involve any complicated technic or the use of high powers, and a series of time-consuming cultures is entirely unnecessary. The determination is most readily made from fresh material, and, while it should be repeated several times in order to exclude all possibility of deception or accident, it requires only a brief time and the use of comparatively low magnification. A consideration of the factors involved will make the matter clearer.

Evidence of the presence of parasites will ordinarily be obtained by an examination of the blood, sputum, urine or feces. The first three are very frequently examined in the diagnosis of disease, and, as a matter of fact, they rarely furnish evidence of parasitism. So far as I have been able to learn, fecal examinations are rarely made, and yet by them evidence of parasitism would be most largely furnished.

By means of such examination one finds sometimes specimens of the entire adult parasite; again, recognizable fragments of the same, its embryos, or its eggs. It is comparatively rarely that one encounters specimens of the entire parasite, and unless the latter is very abundant, such specimens may easily be overlooked if not of such size as to be readily visible to the naked eye.

The identification of the parasite by some recognizable fragment of the body is regularly made only in the case of the tapeworm, which is determined by the passing of segments or proglottids at stools. While the precise determination of the species of tapeworm from the separate proglottids is often a matter of more difficulty than ordinarily believed, the cases of confusion resulting therefrom are not such as to introduce any difficulties in the accepted treatment. In passing, it may be noted, however, that the determination of tapeworm proglottids as flukes on account of their active independent movements is a frequent error. The examination of such structures, even with a hand lens, will show the absence of features characteristic of the flukes.

The determination of embryos is not attended with difficulties, so far as the different groups are concerned. The individual species of *Filaria* have been but little studied, and are imperfectly known. These forms are probably rare in our fauna, unless it be in the Southern states, and methods of coping with them are yet to be worked out.

It is ordinarily with the eggs of parasites, if found at all, that the greatest difficulties in precise determination are experienced. This is, in large part, due to the inaccurate and insufficient knowledge concerning them. A comparison of the original sources with various manuals shows that serious errors in measurement have crept in and that mention of important and characteristic peculiarities has often been omitted. I have, accordingly, published elsewhere[5] a critical review of these features, with illustrations to which those interested may be referred for details. Here it is possible to review only certain general features.

The eggs of parasites may be distinguished on the basis of form, size, texture and other individual peculiarities. Any one of these elements is usually insufficient for specific distinction; but, with the exception of a few forms of rare occurrence which are imperfectly known, the group of characters enables one to make a determination. In reaching a decision, the observer should, however, keep in mind certain general points. In the case of tapeworm eggs, there are sometimes external membranes of a deciduous or variable character. Their presence in an extended or in a shrunken condition, or their absence, may alter greatly the external appearance of the eggs; the appearance and size of the inner membrane and of the included embryo are, however, relatively constant. The eggs of flukes and of

5. Ward, H. B.: Data for the Determination of Human Parasites, Trans. Amer. Micros. Soc., vol. xxiv, 1903.

round worms have only a single firm shell of chitinous character, and are in color usually a faint yellowish-brown, varying to darker brown. As the shell is firm, it can not be materially modified in size by pressure, although since the increase in width is relatively much greater, the proportions are noticeably altered. All eggs are not mathematically uniform in size; the range of variation is in most cases small, and the average readily obtained by measuring ten or a dozen specimens taken at random. The same comparison of a number of specimens will serve to eliminate abnormalities of the individual egg and to give a correct idea of the typical structure.

It is necessary now to call attention to possible results of the examination in the way of non-agreement of the forms discovered with the data at present known regarding human parasites. Such non-agreement may, of course, point to the discovery of a form new to the world, and most frequently has resulted in the description of the form under these conditions as a new species which has been duly baptized. Unfortunately, there are two other possibilities which are more frequently met with than the one just cited, and a disregard of them has led to great confusion. It may be, in the first place, that the species is new to the human host, but is one which is known from some other host. It, consequently, should not receive a new name, but should be discussed merely in the light of its occurrence under these conditions heretofore unknown. Such a species may be normal to the human host as well as to that from which it was previously known, but a considerable range of cases must be brought forward in order to demonstrate this fact. When only a single case of the occurrence of the parasite is determined, such new forms fall more frequently into the categories known as occasional parasites, and accidental parasites.

One may recognize among human parasites those which occur in their normal host, but in an unusual location, like the brain cysticerci; there are also many of the species listed which can not be regarded in any way as characteristic of the human host. Such are the occasional parasites which are species of true parasitic habit and able to attain normal development in the human host, but ordinarily not finding conditions favorable for their introduction. As an instance of such species may be mentioned *Fasciola hepatica,* the common liver fluke of the sheep, which in many regions of the world is extraordinarily abundant. That it can thrive in the human system is demonstrated by the score or more of definitely recorded cases of its occurrence there, but its infrequence is equal evidence of a general immunity on the part of man, lacking in these particular cases, or of some special feature in its life history which makes the infection of the human host difficult. That the latter is the probable explanation may be inferred from the fact that the cercaria larva, liberated from the intermediate host, encysts on plants and, hence, could only reach the human alimentary canal under unusual circumstances. Similar examples may be taken from other groups of parasitic forms, such as the rare occurrence in man of *Strongylus apri,* one of the commonest parasites of the pig in Europe, or of *Dipylidium caninum,* the cosmopolitan tapeworm of both dog and cat which has been reported only rarely from man.

Such occasional parasites often occur under abnormal conditions; thus, a fish nematode, *Ascaris clavata,* was discovered once in the hollow tooth of a man. Here the position was probably accidental, but in other cases it is the result of the action of the parasite itself. So the red spiders, or "jigger" mites, of the central states bury themselves in the skin of man, although such a position is so clearly abnormal that, in fact, it destroys the chance of development and costs the parasite its life. A small leech, *Limnotis nilotica,* common in the circum-Mediterranean area, is often drawn into the throats of men and other animals drinking at wayside pools. It usually retains its position, causing serious difficulty, until removed by operative interference; hence it has become an occasional parasite of man rather than as most leeches, a temporary parasite; or one may regard it as falling in the next following group of accidental parasites. This example shows most clearly the narrow and somewhat artificial limits which separate these groups of parasites from one another. Of the mites also which have been reported a few times as obtained living from stomach, bladder and rectum, it is difficult to say whether they are occasional or accidental parasites of man.

There are also, rarely, other forms which usually occur free living, but which by chance are introduced into some organ in which conditions are such that they can thrive. They become thus accidental parasites, a group difficult practically to distinguish from the last, the occasional parasites, and yet presenting somewhat different biologic conditions. The recent discovery by Stiles and Frankland, as well as others, of the vinegar eel, *Anguillula aceti,* as an apparently successful colonizer of the bladder in a female patient, illustrates the type under consideration. There is little doubt that this parasite was introduced through the use of vinegar in vaginal douches and effected a successful colonization, possibly by virtue of the trace of albumin present in the urine which furnished the worms with nourishment. Equally striking is the case of Scheiber, who discovered *Pelodera pellio* in the urine of a female patient in Hungary. This typical slime-inhabiting nematode gained entrance no doubt through the application of mud poultices, which are commonly employed by peasants in that region. It should be noticed that such accidental parasites are necessarily confined to those groups of animals which have free living forms. Such are *Protozoa, Nematoda* and, perhaps, *Insecta* in the larval condition, while *Cestoda* and *Trematoda,* which live only as parasitic forms in some host, would become rather occasional parasites of man should they stray into the human system in some chance manner and find favorable conditions for existence.

Another type of animals found in man is quite distinct from those just considered. They are known as pseudoparasites and rank high in clinical importance. Among them one may recognize several very distinct classes. First, those which are actually free living animals, introduced by accident, usually in food or drink, into the human alimentary canal, and exciting there abnormal conditions which induce their more or less immediate and forcible expulsion. Thus Botkin found in the vomit of a Russian numbers of a small nematode which he wrongly believed to be a human parasite. In fact, it lives normally in the onion, and its introduction into the stomach with this food excited the untoward symptoms noted. Similarly, Blanchard records a case in which coleopterous larvæ were found in the vomit of a child.

That such may be the result of introducing a true parasite from some other host is indicated by several cases like that of *Ascaris maritima,* which Leuckart described from a single specimen vomited by a child in Greenland and which this author noted was very simi-

lar to *A. transfuga* of the brown bear. In all probability it was ingested with the viscera of some animal (seal?), though it may have been a species which had strayed into this unusual host only to make its appearance under the circumstances noted.

Of similar import are the cases of *Gordius*, the hair snake, which have been reported from man. In the adult condition this is normally a free living species, but about a dozen specimens have been taken from man after a supposed sojourn of from a few hours to fourteen days. Some of these have been vomited and others passed per anum. This form has often been passed off on the physician as a true parasite, and in one celebrated case at least as the Guinea worm.

In the same way one may find the explanation for other isolated cases of parasitism, even when the parasite is reported to have been passed from the alimentary canal. Thus Cobbold reported that larvæ of *Blaps mortisaga*, the English churchyard beetle, were found in fecal discharges, and many authors have recorded the presence of dipterous larvæ in the alimentary canal.

The majority of such observers has inclined to regard the larvæ as temporary endoparasites and to consider that they have accommodated themselves to the conditions present in the human host. Certain cases seem to show that these larvæ live for some time in the canal and often appear to evoke serious or even fatal disturbances; and yet the conclusions are open to grave doubt, for Calandruccio experimented extensively on two families, to which many of the supposed accidental parasites belong, and found that the ingested larvæ were regularly and promptly evacuated dead or dying, and in no case secured a footing in the canal.

Among the myriopods, about 40 recorded cases of pseudoparasitism have been brought together and discussed by Blanchard. In the large majority the animal was taken from the nasal fossæ, though in a smaller number it was actually obtained living from the alimentary canal, where it undoubtedly can exist for a brief time in spite of the untoward environment. The ingestion of such forms is purely accidental, the symptoms those of helminthiasis in general, and their stay at most very limited. They never show any evidence of adaptation to the new environment.

In some such accidental fashion other forms are sometimes introduced into various organs not connected with the alimentary system. Thus Trouessart reported the occurrence of a species of detricolous sarcoptids in the human testicle, where the mites formed an old colony in a painless cystic tumor.

In addition to the living animals of the types noted, the second class of pseudoparasites includes a large number of other structures which have been described as parasites. These may be considered conveniently in a few groups, the first of which includes bodies which are parts of the so-called host animal itself. Thus fragments of the arteria hyaloidea have been described as eye worms (*Filaria lentis, F. oculi-humani,* etc.); the supposed organisms of whooping cough are nothing more nor less than ciliated tracheal cells torn from the wall and found in the sputum in distorted form, while groups of small axillary and inguinal glands, hydatid moles and pacchionian bodies from the arachnoid have been frequently put on record as hydatid cysts.

Parts of substances used as food, both of plant and of animal origin, which have not been destroyed by the action of digestive juices, are also among the pseudoparasites of man. The radulæ of the common limpet have been reported several times from stools; the seeds of the mulberry were duly baptized as parasitic worms; and plant vessels and other similar undigested structures of peculiar appearance appear periodically as new helminths. That a differentiation of such structures is not simple appears from the account given by Stiles of the partially digested banana fibers, which closely simulate minute tapeworms. Some years ago Leuckart entrapped a group of research students in helminthology with the pulp vesicles of an orange which were found in a fecal examination.

In all of the cases considered above, it has been presupposed that the structures obtained actually came from within the human body. It is necessary, however, that the physician should have personal evidence of this, for there is another class of objects of which it can not be said. And these structures deserve brief mention in closing.

In determining the nature of unusual forms reported from man, it should always be kept in mind that in the absence of positive personal evidence, suspicion in cases of neurasthenia at least favors the deceitful introduction of such doubtful bodies. In many cases on record such things as earthworms, chicken entrails, etc., have been forcibly introduced into the rectum or vagina and have been subsequently reported by the attending physician as undoubted human entozoa of a remarkable character! Here, as elsewhere, the appearance of unusual structures should at once arouse the suspicion of the physician and call forth a most searching examination of the case in all its factors that any deceit be disclosed, or that in the event of the discovery of some rare parasite all conditions connected with its appearance be put on record for future use. Furthermore, it is important to preserve the fullest data in regard to any substances associated with it, as well as the food of the patient, whether usual or unusual, since in this way some hint as to the introduction of the supposed parasite may be found.

Finally, it is important to direct attention to the wisdom of preserving all doubtful material, whether new or not, in considerable quantities, and both the eggs and embryos, as well as the adults, or as many thereof as can be obtained. In case of doubt regarding the identification of species, or possible question as to the source, it is important that the material or some portion of it should be referred to some expert helminthologist for examination and verification of the result attained. It is always a pleasure to have the opportunity of examining such material, and to assist one's colleagues in any way in connection with such studies. In most cases, in fact, and especially such as deal with the occurrence of rare forms, or such as are new, it is desirable that such corroborative evidence should be secured before publication, for in this way is often prevented the confusion which arises from incorrect descriptions or from the publication of new names which are merely synonymous with those already known to science. As a matter of fact, the practitioner can hardly hope to be acquainted with the entire range of parasitic species, and if to the accurate observations which he records regarding the clinical side of the question can be appended the notes of some helminthologist who is in a position to give an expert opinion regarding the other side, the results are far more valuable to the world from their rounded scientific character and permanent value, than could be attained by the publication of either group of factors separately.

The large number of parasites in other animals which some unusual combination of circumstances may bring

into the human system makes it imperative that any supposedly new species be submitted to the judgment of a specialist before it is described as such. Only in this way can the discoverer avoid adding to the long list of synonyms which already burden the literature of this subject and render it so difficult for the investigator not a specialist in this particular line to find his way aright.

DISCUSSION.

DR. FRANK B. WYNN, Indianapolis—First, I want to refer to a clinical case in the practice of W. B. Fletcher of Indianapolis. A patient had suffered for a long period from seizures of an epileptic nature of severe type. Segments of tapeworms were found in the stools. After the administration of proper remedies the parasite was expelled and the patient had complete relief from all symptoms.

A word in reference to spurious helminths. I recently had sent to me by a physician worms alleged to have been passed in the stools of a woman. They were the larvæ of the bluebottle fly. As she was said to be passing these in large numbers, I asked for a second sample and found them different from the first. A third supply revealed still a different species. So my first suspicions were confirmed, that a hysterical patient was practicing deception on the Doctor.

Dr. Ward has referred to one feature of great practical importance, which I should like to emphasize if possible, and that is the errors of practitioners in dealing with supposed intestinal parasites. Some two years ago I received from a doctor some little dark threads, passed in the stools of a patient and thought to be worms. Since then I have received two other specimens, identically similar from different patients. Under the microscope were to be seen chains of large, amber-colored oval bodies. My first impression was that they were uric acid nuggets formed on a cotton fibril in the vessel where the excreta had been passed, and that the sharp points of the crystals had been dissolved off as the urine became alkaline. By and by I found spirals, proving the vegetable character of the bodies. The next point of interest to determine was from what vegetable they came. In conjunction with my botanical friend, John S. Wright, it was soon demonstrated that these dark strings were of the fibrovascular tissue of the banana, especially the older fruit near the core. Age or light leads to pigmentation of the rows of large parenchyma cells along the strings of fibrovascular tissue. (The specimens exhibited were reported to the Indianapolis Medical Society about two years ago.)

Shortly after this investigation I received another specimen supposed to be tapeworm. The segments were too long and slender, however, and instead of being square cut were oblique at the ends. I suspected they were vegetable in character, and on investigation they were proven to be cabbage, prepared as slaw. (Specimen exhibited.)

I want to call attention to another structure not rarely found in the stools which I had some difficulty in running down. Dr. Ward informs me that he had a similar experience. I refer to the fusiform and attenuated masses of cells found in the lemon and orange, which are not unlike the fluke. Some were sent to me two years ago, supposed to be parasites.

These experiences led me to start some of my students in the medical department of the University of Indianapolis to studying some of the more common fruits and vegetables used as articles of diet. The results are presented in the Scientific Exhibit. First, sections were prepared of crude vegetable or fruit. Secondly, fresh glycerin mounts were made of the same articles, as found on the table ready for eating. And thirdly, each student ate abundantly of the article assigned, and afterward his stools were carefully examined for remnants of the food taken. We found that a number of these examinations showed products which might easily be mistaken for parasites. The fibrovascular threads of the pineapple, rhubarb and celery are particularly apt to mislead, as will be readily appreciated from the specimens here exhibited.

The specimen I have here came from my own stools. I was surprised to find these long flakes, not unlike tapeworms. It proves to be paper. Paper intimately adherent to candy, meat from the butcher shop, bread, etc., is often swallowed unconsciously, is wholly indigestible and might be mistaken for the segments of tapeworm or membranous exfoliation of colitis.

DR. WALTER L. BIERRING, Iowa City, Iowa—In connection with the remarks made by Dr. Wynn, I would like to refer to an experience with the spurious tapeworm disease in Iowa during the past winter. Two specimens of material were sent to me from different parts of the state, in both cases being derived from the stools of children 5 years of age. Periodical attacks of indigestion were noted and when this tapeworm-like material was passed the child in each instance improved. One of the specimens came from one of the best physicians of our state, who entertained an idea that it might be a case of *Tænia nana* infection. After repeated examination of the material and suspecting it to be some vegetable fiber, I referred it to Dr. Stiles of Washington, who informed me that the tapeworm-like material was composed of undigested banana fibers. For the purpose of corroboration various tests were made in the pathologic laboratory, one of which consisted in giving test meals of banana and finding the dark-colored segmented fibers subsequently in the stool, and the other consisted in applying a 10 per cent. solution of potassium hydrate to banana, which brought the transverse fibers of the banana that are evidently indigestible out very prominently, also giving to them the dark color which they usually attain on exposure to the light.

DR. ALLEN J. SMITH, Galveston, Texas—I have found that almost every living thing is possessed of some parasite, and they have a widespread pathogenic influence. The subject is one obtaining greater recognition within recent years, as shown by the increasing prominence given it in pathologic text-books; but as yet in this country it has by no means had sufficient stress laid on it. There is not as yet sufficient demand for information on the lines of the paper just read to have called forth a single good text-book in our language. There are a number of excellent German and French works dealing in an authoritative and systematic manner with human and comparative zoöparasitology, but none in our own tongue (except the work written by Neumann for veterinarians and translated from the German). Within the past three years I have approached no less than six of the more prominent American medical book publishers with a proposition to publish a translation of Railliet's *Traite de Zoologie médicale et agricole*, but all declined on the ground of financial danger. I regret my failure, as the work in hand of many practitioners in this country really presents a great need for some standard work of the kind. As an illustration of the importance of the general subject, I call attention to the recent work of a number of observers in relation to the new American hookworm, *Uncinaria americana* (Stiles); a parasite first discovered in Galveston, and since then met by a number of observers in the southern and eastern parts of the country. The excellent work of Stiles, of the United States Public Health and Marine-Hospital Service, has demonstrated how this parasite is probably wholly or at least largely responsible for the miserable state of the well-known "poor whites," known so widely as dirt "eaters" in these districts, pale, large-bellied and thin, for the inertness and laziness for which they are so much criticised, as well as for really serious pathologic conditions in these people. Aside from its proper influences this parasite seems to seriously influence and perhaps modify the course of other diseases with which it may be associated; for example, it probably is an influence making malaria more persistent. From observations of my own, where the uncinaria and malarial parasites coexisted, I have noted the difficulty in getting rid of the malarial infection by the usual use of quinin until the intestinal parasites have been disposed of—a relationship perhaps depending on the influence of the latter in keeping at a low ebb the natural antagonistic powers of the body against the malarial organisms and thus permitting redevelopment of any hematozoa remaining after a course of quinin administration. This I have

so persistently noted that I feel the importance of seeking the coexistence of these intestinal parasites in the particularly obstinate, chronic and recurrent forms of malaria in these southern districts as possible influences in the clinical course of such a case.

Another example of the importance of the subject is the recent discovery in Texas and elsewhere of *Tænia nana*, a tapeworm known to be responsible for considerable intestinal disturbance, for the development of pernicious anemia and in various instances of epileptiform phenomena. Such instances of the importance of animal parasites might be indefinitely multiplied; and the importance of this branch of pathology is manifesting itself more and more as time goes on. The field, however, has by no means received the attention its importance deserves; and for one I feel anxious that it shall soon be represented by some adequate reference work in our own language, or some translation of one of the worthy European works annotated from an American standpoint.

DR. H. B. WARD, Lincoln, Neb.—I think Dr. Wynn's date of two years is the record for the banana fibers, though within that time Stiles of Washington, Bierring of Iowa and a number of men in different parts of the country have made the same discovery. One case to which I did not refer in the paper came to me last year in Nebraska, which has the further interest that the physician said it was a remarkable case of tapeworm, as it was found in the alimentary canal and also in the vagina.

One thing I should like to emphasize in closing. It has been mentioned again and again to-day in this and in other sections that there is a sad lack of fecal examinations. Last year a very well educated and a very bright and thoughtful physician in a city not my own permitted a patient to die of pernicious anemia without a single fecal examination.

UNCINARIASIS IN THE SOUTH.

FURTHER OBSERVATIONS.*

CLAUDE A. SMITH, M.D.

Pathologist to Grady Hospital; Demonstrator of Pathology and Bacteriology, Atlanta College of Physicians and Surgeons; Professor of Pathology and Bacteriology, Southern Dental College.

ATLANTA, GA.

Since presenting the paper before this Section at the meeting in Saratoga last year, in which I reported three cases of ankylostomiasis, or uncinariasis, the first case being found postmortem, in December, 1901, and the other two being mild cases found among the negro convicts working in the brickyards near Atlanta, I have found this disease to be exceedingly common from the Carolinas to Texas. I make this statement as a result of examinations of medical students at the Atlanta College of Physicians and Surgeons, at the Southern Dental College, patients sent to Atlanta from the adjoining states and a systematic examination of all the patients in the Grady Hospital for the past year. However, very few cases have appeared at the Grady Hospital for the reason that all the patients in the public wards must be residents of Atlanta, and, as this is a disease of the country and not of the city, we would not, therefore, expect to find many in the hospital. Since the postmortem on the case reported last year, I have made fifty postmortem examinations at the hospital, and among these have had only one case of uncinariasis.

This disease is found in the mountains as well as in the lowlands, but is more common the farther south you go, as the conditions for the production and development of the larvæ are more favorable. The disease is very common in regions where the chances of contamination of the drinking water with surface drainage is very slight.

The disease may occur at any age, but is more commonly found in children. The cases seen by me range from three years to over fifty years of age. It is more common in males than females, and is usually found among the children of the lower classes, but I have seen several cases among the better class. It appears to be more frequent among the whites than the negroes. It is a disease of the country, and the possibility of its presence should be considered in all patients who give a history of having resided in the country or small villages within seven or eight years. It prevails where unsanitary conditions abound.

The eggs of the parasite are passed in the feces of persons affected with the disease, and these feces, being deposited about on the earth, furnish the original source of infection. The life history of the parasite found in the dog and the one found in man is very similar, but I have not been able to infect one from the other.

I have found the eggs in the stools of a dog, and a careful postmortem examination showed only three of the worms in the intestine of the dog. This shows that no matter how small the number of worms may be, it is possible to find the eggs in the feces. Practically, the same thing applies to the parasite found in the human intestine, as one case disclosed only seven worms postmortem. It is possible for one experienced in making these examinations to give a fair idea of the number of worms in the intestine from the number of eggs appearing in the stools. They can be estimated with a greater degree of accuracy in this way than by the symptoms of the patient, as a comparatively small number in one person will produce severer symptoms than a larger number in another person.

A live uncinaria removed from a dog under chloroform was seen by me to discharge 22 eggs in one minute, and while this was taking place there was no appreciable diminution in the quantity of eggs contained in the uterus of the worm. This gives us some idea of the great number of eggs which may be thrown off by one worm.

As a rule, the eggs do not hatch while in the intestines. I have found the larvæ hatched out in only two specimens of feces. Usually, it is necessary for the eggs to become mixed with earth before they will begin to hatch; that is, they seem to need air. The eggs can be hatched without any difficulty if the feces containing the eggs are mixed with sufficient earth or sand to destroy the odor of the feces. They will hatch in from twelve to twenty-four hours, or longer, depending on the temperature and moisture; too much moisture inhibiting their development.

They are destroyed by freezing, as also by drying, but they must be thoroughly dry, the least bit of moisture preserving them. Feces which are perfectly dry on the outside will be found to be moist in the interior and the eggs there still preserving their vitality. In warm weather, if the eggs are kept in moist feces, I have been unable to hatch any of them after two weeks. In hatching, I have observed the larva emerge tail first from the egg.

For the first day or so the larva is rather sluggish, but as the first sheath appears it becomes more energetic and is extremely lively at times. If in water alone it wiggles at a lively rate, but does not make much headway, but if imbedded in earth or sand, where it can obtain a foothold, by a sinuous motion it darts through sand at a lively rate. These periods of activity are of

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. L. Hektoen, F. B. Wynn and W. S. Hall.

variable duration. The larva will move quite lively for from a few minutes to half an hour or more, and then it will straighten out and lie perfectly still for a corresponding length of time.

Freezing destroys the larvæ, as will also drying. However, it should be remembered that soil which to the naked eye appears perfectly dry will, on examination with the microscope, be found to contain a small amount of moisture, and such an amount as is sufficient to preserve the vitality of the larvæ. But, if they do become thoroughly dried, if only for a moment, they can not be revived. Knowledge of the conditions under which these larvæ exist are of great value in determining when and how the disease may be contracted. When we remember that it freezes every winter throughout the South down through the northern part of Florida, we can readily see that the disease could not be contracted in the winter; also, as drying destroys the larvæ, their existence is a very precarious one. However, during the warm summer months, when there is a rainy spell, the ideal conditions prevail for the development of the larvæ, and so this is the time at which we would be most likely to encounter them.

The next point which concerns us is, how do they reach the intestinal canal? It was not suspected until the last few years that it could reach the intestines other than through the mouth, and especially as moisture is necessary for the existence of the parasite it was supposed to gain entrance principally through drinking water. However, since Looss has demonstrated that the larvæ may pass through the skin, and Bentley has attributed the pani-ghao, or ground itch, to the larvæ, it has opened up new avenues for investigation. At first consideration of this view I was loath to believe that the parasite could gain entrance by passage through the skin, as it appeared to me more probable that it made entrance through drinking water. But after a careful observation and investigation of the habits of the larvæ and of the disease itself as it exists, I was forced to the opinion that in the great majority of cases they gain entrance through the skin of the feet, and that the true ground itch is simply the manifestation of this passage. There is no doubt that some cases may be produced through drinking water, but my observations of the development of the larvæ and the conditions surrounding the disease have led me to believe that this is the exception and not the rule. That infection could take place through dirt on the hands and then taken into the mouth I am also inclined to believe is the exception, even more so than infection through drinking water, for it is likely that the larvæ would become destroyed by drying before they would be taken into the mouth.

Ground itch is the most common disease in the South, and the majority of cases are never carried to the physician, but are treated with home remedies. It appears in the summer and always as a result of going barefoot in wet weather. In many sections in the South it is thought to be the result of being poisoned by the dew, but it is always contracted at the time when the ground is damp, which is the condition most favorable to the development of the larvæ of the uncinaria. In some districts they take great pains to try to keep the children indoors during rainy weather, and especially when it rains several days, so as to prevent them from having this ground itch. One patient told me that he was fond of wading in ditches after a rain, and he was sure that the foam which collected along the sides of the ditches contained the "poison," as he always had an attack from wading in that foam.

The first symptom of ground itch is an itching between the toes, which begins after going barefoot in the mud. It may appear at one place between two toes, or it may appear between all of the toes, and also under them, and in some cases may extend up some distance on the foot. This itching increases and the skin becomes very red, and finally small vesicles are formed. The itching continues and these vesicles are usually ruptured, leaving a raw weeping surface. The itching is generally excruciating, and the condition may last two, three, four or more weeks.

The following is some of the evidence in favor of the ground itch being the method of entrance into the human body of the larvæ:

Every person who has had true ground itch within seven or eight years will have the eggs of the parasite

Case 1.—17 years of age. Case 2.—15 years of age.

These two are brothers. Examination of stools showed a great number of eggs of uncinaria in stools of No. 1, and comparatively few in stools of No. 2. This illustrates the lack of development in the extreme type of uncinariasis. No. 1 is two years older than No. 2, yet presented the appearance of a boy of 12 years, with no development of sexual organs. No. 1 is unable to do any work, while No. 2 is apparently as vigorous as other boys.

in their stools. This time limit is not positive as yet, but the evidence points strongly to a limit of about seven years.

You can form a fair estimate of the number of eggs that you will find in the stools by taking a careful history of the severity and extent of the number of attacks of ground itch. For example, if a patient gives a history of having had a number of attacks of ground itch which involved all of the toes and possibly a portion of the feet, you will find a great number of eggs in the stools of that patient. In the last postmortem in which I found the uncinaria in the intestines, I saw the patient

just two days before her death, and in getting her history learned that she had had an attack of ground itch about four or five years previously, but she informed me that she did not have it very bad, as it existed only in one place between two toes. A careful search at the postmortem examination disclosed only seven of the worms. I have seen only two cases of the disease which did not give a history of having had ground itch within seven years. They were two dental students who lived at the same place in Florida, and they were both sure that they had not had ground itch for fourteen or fifteen years. However, their drinking water was obtained from wells only three or four feet deep and which overflowed every time it rained. These were probably infected through drinking water, but in both cases the infection was very slight, as it required careful search to find the eggs in the stools, as they were so very few in number.

Case 3.—White; male; age 17. Skin resembles yellow parchment; mucous membranes blanched; appetite poor; sleeps fairly well; has severe griping of bowels at times; badly constipated. Red corpuscles, 1,672,000; hemoglobin, 22 per cent. Notice lack of development of sexual organs. Has had "ground-itch" so many times that can not recall any year that he did not have it. Stools contain eggs of uncinaria in great numbers. Barely able to get about, and unable to do any work.

Many of the cases of the disease were suspected and located only on finding a history of having had ground itch within seven years. One was a medical student from the mountains of South Carolina, who presented a picture of perfect health, with a ruddy complexion, and who did not suspect that he had uncinariasis until he overheard a conversation about the relation of ground itch to the disease. He then came to me and told me that he had had a severe attack of ground itch about five or six years before, and on examination of his stools I found numerous eggs of the uncinaria. Examination of his blood showed: red corpuscles, 4,120,000, and hemoglobin, 95 per cent. After two doses of thymol of one gram each, eighteen uncinaria were found in his stools and no eggs were found a week later. It usually requires several attacks of ground itch, extending over a period of several summers, for sufficient numbers of the larvæ to get into the system to produce the extreme type of the disease.

A careful examination was made of all the members of a family of eight who had lived under the same conditions, drinking the same water, etc., and this showed that those who had been keeping the feet protected for over eight years by wearing shoes, and who had not had ground itch during that time, did not have the eggs in their stools, while all who had had ground itch within that time had the eggs in quantities in direct proportion to the number and severity of the attacks of ground itch.

You may take the history of some of the cases which have at one time been in the extreme stage, and you will find that they had attacks of ground itch year after year, or probably skipping a year now and then, and they would get worse from year to year until they had had attacks covering a period of seven years or more, and

Case 4.—White; male; age 7. Skin yellowish-white; mucous membranes blanched; appetite poor and perverted; bowels constipated; shortness of breath; loud hemic murmur; can not walk over 200 yards at a time; headache and vomiting every morning; stools contain an abundance of eggs of uncinaria. Red corpuscles, 1,208,000; hemoglobin, 10 per cent. Has had "ground-itch" every year since able to walk. Has had whooping cough, but no other sickness.

probably they were old enough by that time to begin wearing shoes in the summer time, and, therefore, those parasites which first gained entrance into the body would have passed through their allotted period of existence and would die out, and by the patient wearing shoes, additional larvæ would fail to get into the body, and as each following year more and more of the uncinaria would die out, the patient will give a history of gradual improvement, and his body will begin to take on a vigorous development. There is no difficulty in finding plenty of these cases which give a history of having once been extremely pale and anemic, but have "outgrown" it.

The disease gradually disappears after they stop going barefoot.

The number of the uncinaria in the intestines varies from a few to several hundred. The number is nearly always in direct proportion to the number and severity of attacks of ground itch. A few of the uncinaria may produce no apparent effect on the patient, but it no doubt renders the patient more susceptible to infection as a result of the interference with the nutrition. Severe infections produce various grades of anemia. The blood counts show all stages; some being so severe as to produce dizziness, hemic murmurs and the weakness which accompanies such conditions. These extreme cases are usually emaciated, but the emaciation may not be apparent at first on account of edema. In the extreme cases the skin is of a yellowish-white parchment color, and over the exposed portions of the body, as the cheeks and hands, it appears to be much thickened. The mucous membrane also presents a yellowish-white blanched appearance, and examination of the blood often shows the red corpuscles as low as 1,100,000, and the hemoglobin down to 10 and 15 per cent. If this severe condition is reached about the time of puberty, the sexual development does not take place, and it is not uncommon to see boys 17 and 18 years of age who are dwarfed and whose genital organs have the same appearance as those of a boy about 10 years of age. Also, you will find girls 18 years of age in whom there has never been any effort at menstruation, and who present no evidence of development into womanhood. We must remember that these are the extreme cases. They are the ones which give a history of numerous and severe attacks of ground itch, usually having it for a number of years, and members of the same family who are living under exactly the same conditions, but who have not had so many, nor such severe, attacks of ground itch will have only a small number of parasites in their intestines, and practically no interference with their development.

It is a most pitiable sight to see these severe cases in bright children who are unable to walk 200 yards without being almost completely exhausted and who have to sit down and rest before they can go further. They are unable to play the games with other children, but must drag out their lives sitting and lying around, watching the other children in their games and yearning for the strength to join in with them. Sometimes they succumb to additional infection of the uncinaria, or to attacks of other diseases.

In their earnest desire to be cured and become strong like other children, they are willing to undergo any treatment which will offer any chance of doing them good, and often you will find that they have made the rounds of all physicians in their district, but to no avail. I recall the case of one poor boy who was barely able to drag himself about, and on being told that there was a chance of something being done for him, he arose early in the morning only to find that the rain was pouring in torrents, but, nothing daunted, he dragged himself all alone three miles through the pouring rain to the physician's office, drenched to the skin and shivering with cold, but willing and anxious to begin at once with any treatment that offered any chance of doing him good. That was only three weeks ago, and since then his improvement has been remarkable, as he is now at work again on the farm.

Every country practitioner in the South has more or less of these cases of anemia in his practice, and sometimes they will improve slightly with prescriptions of iron, arsenic, etc., but with no permanent results.

The poor farmers throughout the country who have a house full of children to support are dependent to a great extent on the assistance of these children to make sufficient for their maintenance, and when the children are affected with this disease and are unable to assist him to any extent, but rather instead are a burden to him to pay their physician's bills and supply medicine—these are the ones who often seek the cotton mill, where most of the children, although dwarfed and stunted and incapable of severe exertion, yet have sufficient strength to sit at a loom and do light work about the mills. While it is deplorable that child labor is not better controlled, and, while I believe in giving the devil his dues, yet we should, at the same time, be just, for no doubt many of the cases of children whose lives are supposed to be blighted in the cotton mills, were blighted before they went there, and the confinement and tedious work is but assisting in the work of destruction already begun.

We read our statistics of the destruction wrought by the dreaded tuberculosis and pneumonia, etc., but we have here a disease which is literally sapping the life-blood of the South. But, unlike tuberculosis and pneumonia, etc., we have for this terrible disease an easy means of diagnosis, and a cure which is simple and certain. All that is necessary is for the physicians throughout the country to become familiar with the diagnosis and treatment.

Before treatment is instituted, a positive diagnosis can only be made by the examination of the stools for the eggs, and one experienced in examining these stools with the microscope can get a better idea of the number of parasites in the intestines than from the symptoms of the patient.

The treatment is very simple, but to be thoroughly effective certain precautions should be observed. Two doses of thymol finely powdered of one or two grams each are to be given about two hours apart. The first dose should be preceded several hours by a dose of some purgative, and followed by the same. One very important point is that no food must be taken into the stomach from the time of the first dose of the purgative until after the second is taken. The plan is as follows: A large dose of salts is given at night and the next morning at 8 o'clock two grams of *finely powdered* thymol is given, and two hours later a second dose of two grams, and two hours after this a large dose of salts is given. I lay stress on having the thymol finely powdered and no food being taken into the stomach between the administration of the purgatives. In some instances this treatment is not thoroughly effective, and a microscopic examination of the stools should always be made about a week later, and if eggs are still present, the treatment should be repeated.

In the postmortem examinations of the human intestines containing the uncinaria, I have noticed that the parasite is not so firmly attached to the intestinal mucous membrane, and also that it does not seem to lacerate the mucous membrane, or leave the white central spot with the hemorrhagic area surrounding it, as described of the old world parasite, and also of the parasite in the dog. We can readily understand this when we bear in mind the structure of the oral cavity of the uncinaria, as given by Dr. Stiles, showing that it does not have the little hooklets which are found in the old world parasite and the dog in this country, and, therefore, does not become so firmly attached or so severely lacerate the mucous membrane.

The prophylaxis of this disease is very simple. It is not necessary to boil the water for drinking purposes,

unless the water has been contaminated by surface drainage after a rain. If every person will wear shoes which thoroughly protect the feet in rainy weather or in damp places, there is very little chance of infection.

To determine whether the parasite which infects the dog in my section would exist in the human body, I administered successive doses of the larvæ of this parasite to a negro boy 19 years of age (of course, with his consent), beginning the first dose July 11, 1902, when the larvæ were four days old, and continuing about every two weeks until October 14, using larvæ from the original culture made July 7. The patient disappeared October 14, but examinations of stools two days before that were negative.

In making these investigations, I was much indebted to Dr. S. H. Green of Bolton, Ga., and Dr. C. D. Redding of Warthen, Ga.; also to Drs. J. A. Randall, W. E. Persons, C. D. Jeffries, O. T. White and W. A. Selman, of the resident staff of Grady Hospital.

DISCUSSION.

DR. H. B. WARD, Lincoln, Neb.—Dr. Smith has gone further than any other investigator with reference to the life history. It is of the utmost importance that the method of introduction into the body should be known, as well as the interval between the various stages of development. Dr. Smith has investigated the relation between ankylostomiasis and ground itch so thoroughly as to leave little doubt as to their probable connection. I think the probability is very strong indeed. One of the latest investigators records the fact recently in one of the German journals that he has succeeded in infecting the skin with the larvæ. The larvæ were placed on a member which was about to be amputated. When the skin was sectioned after the amputation the larvæ were found to be penetrating the skin along the line of the hair follicles, and they could be made out in the sections. Some had gone in as far as the subdermal tissue. I think that is the first instance where the entrance of the larvæ has been thoroughly established.

Another point deserves brief mention. The experiments of Looss on dogs shows conclusively to my mind that the infection can not be contracted through drinking water. Where the dogs were fed on infected water the larvæ passed through the canal, except a few which bored into the wall of the esophagus and went down into the tissue, where he got the three stages of development. Those which traversed the canal did not attain the adult condition, but those which got into the tissues attained at least the later larval stage.

I presume Dr. Smith has already thought of it, but it would seem to me that in the region where ground itch prevails he might succeed in some postmortem in getting a portion of the tissue from one who had been recently infected with ground itch, and sections made from this would throw light on the subject.

DR. CLAUDE A. SMITH, Atlanta, Ga.—I recognize the fact that the results so far are somewhat incomplete, and that we have not been able yet to obtain positive proof as to the transmission of the disease. Experiments are being still carried on, from which we hope to obtain more satisfactory results. Until then it can not be stated positively that the infection does get into the system through the feet, but from the evidence of cases I have seen I feel positive that this is so.

As to the question of postmortem of subjects who have had ground itch, it must be remembered that these cases are nearly all in the country, and you know how difficult it is to get permission to hold a postmortem in the country, especially in the case of children. They even object sometimes to examination of the stools.

I hope in the near future to be able to present the proof of the transmission of the disease.

OCCURRENCE OF THE STRONGYLOIDES INTESTINALIS IN THE UNITED STATES.

MARSHALL LANGTON PRICE, M.D.
BALTIMORE.

(*Concluded from page 655.*)

RHABDITIFORM EMBRYOS.

As the parasite occurs in the stools as the rhabditiform embryo, and probably never in any form (excepting rarely after a purge, when the passage of the parthenogenetic mother worm has been reported by one or two observers), it follows that the thorough understanding of this form is most essential to diagnosis; and I have, therefore, described it below at some length.

In a properly prepared specimen the embryo appears as a clear, almost hyaline, nematode, completely transparent and possessed of a very active motility, swimming among the granular detritus, and pushing aside the smaller obstacles in its path, and turning aside to pass the larger ones, when its progress is arrested by an obstacle of considerable size. The consistency of the nematode seems scarcely to exceed that of protoplasm, the parasite quivering like jelly with every movement, or when the microscopic stage was jarred or shaken. It appears to possess a considerable degree of irritability, and when aggregated masses of bacteria would lodge against its side, motions of the tail would be produced toward the offending object.

The structure appears granular. The parasite, on examination, is seen to consist of two portions, an outer clear portion or envelope, and an inner granular zone. The outer portion, forming about one-tenth of the transverse diameter of the parasite, is clear and homogeneous, with the exception of a few fine granules. The inner portion is markedly granular and is well organized.

With the death of the parasite the clear homogeneous structure is lost, the granules become larger and coarser and invade the outer envelope. Finally the whole parasite becomes uniformly granular and shrunken, its transparency is largely lost, and all distinction between the envelope and inner granular zone disappears. The parasite appears to undergo a rapidly granular degeneration as soon as dead.

The length of the nematode varies. The average is probably about 0.3 mm., the breadth 0.04 mm. The head is blunt and slightly conical in shape, and contains the anterior portion of the digestive canal. The body gradually enlarges from the head to its middle part, and then gradually diminishes in size to the thick and somewhat pointed tail. The head is largely occupied by the triangular or fusiform darker area of cells surrounding the digestive canal which passes from the cephalic extremity backward. This darker area becomes constricted as soon as the neck is reached, and after running for a variable distance in a uniform size, again expands into an ovoid or spherical area; leaving this, the canal again passes toward the caudal extremity. A slight fusiform dilatation occurs at about the middle of the body, the canal then passes on in its normal size until it reaches the base of the tail, where a saccular dilatation appears. This appearance, which has not been previously described, can be demonstrated in the majority of specimens by careful examination, and no specimen in which the parasites were numerous failed to show one or more in which this structure was evident. The intestine, much diminished in caliber, turns abruptly after leaving this inferior dilatation and passes to the side of the animal, where it terminates in a slight mammilliform projection. Just below the middle of the body, the in-

testine was pushed somewhat to one side by a large oval body, quite refractile and containing rather large granules. This represents the undifferentiated sexual gland. The intestinal contents are plainly visible in the intestinal canal and consist of fluid containing numerous small particles in suspension. Among these can be seen dead bacteria and portions of bacteria and the ordinary granular detritus found in the stools. The motion of the parasite aids the passage of the intestinal contents toward the caudal extremity, but peristalsis has been provided for in another way, to be later described. The motion of the parasite is constant and never ceases, except momentarily; the motion, indeed, seems necessary to the life of the parasite, and when it ceases the parasite soon shrinks and undergoes the granular degeneration already described. The motion of the parasite apparently acts in somewhat the same manner as the cardiovascular system in higher animals in promoting the interchange of the tissue juices.

The minute structure of the digestive system shows many interesting details. The canal begins, in many specimens, in a procephalic projection, which has a cup-shaped depression on its anterior end. The digestive canal passes through this portion, which is transparent and non-granular, and not being especially refractile, is difficult to demonstrate in all specimens. The canal, passing into the head, enters the anterior esophageal expansion, which consists of stratified squamous cells with oval or flattened nuclei. It then passes toward the tail until it reaches the second globular expansion, where it is suddenly lost, plunging, in fact, into the center of this mass. This globular mass is made up of large secreting cells containing fine granules, and a large centrally-placed nucleus. This organ appears analogous to a stomach, and probably furnishes the digestive juices. In the center appears a round, clear area, which is the cavity of the organ showing through the cell mass. It is in this situation that the tridentate chitinous armature described by certain authors makes its appearance. I have never been able to demonstrate any opening in this situation, and have never observed the ingestion or excretion of any of the intestinal contents by means of it. The appearance is like that of the small Greek letter gamma. (The upper limb appears to be formed by the intestinal canal showing through the cells, and the two lower limbs by the interval between two of the large secreting cells, whose angle corresponds to the angle of refraction of the parasite.) As soon as this secreting organ becomes continuous with the intestinal canal (as occurs in the filariform embryo) this appearance at once is lost. About the middle of the body the canal enlarges slightly and extends some distance downward before it again contracts. This portion of the canal is lined by distinct columnar cells with dark nuclei; this appears in analogy with the secreting organ to be the absorptive portion of the parasite.

The digestive canal may at times be seen to suddenly contract longitudinally. The result of this is that a portion of the canal becomes convoluted or S-shaped, and its lumen in this portion becomes narrowed, or even obliterated; acting in this way as an adjunct to the more constant peristalsis produced by the movements of the animal. The effect of the globular dilatation seen at the caudal extremity is presumably to delay the intestinal contents until they can be effectually acted on by the tissue juices.

MORPHOLOGIC VARIATIONS OF RHABDITIFORM EMBRYOS.

The variations of form of the *Strongyloides intestinalis* do not end with the four distinct types mentioned, but the embryonic forms, especially, show a number of other morphologic variations. It is important to realize this fact, as these variations may otherwise be mistaken for different species. Between the two widely varying types of embryos, viz., the filariform and rhabditiform, are found many intermediate forms. The youngest form of embryo is short and thick, the older specimens become longer and thinner, and in the shape of their bodies come to resemble the filariform type. The line of demarcation is, however, distinct between the two types in the structure of their internal organs. In one specimen observed both the filariform and rhabditiform embryos were found in the same specimen with others that in the shape of the body resembled the filariform, but were rhabditiform embryos. No marked variations occur in the filariform type, but variations in the rhabditiform embryos were frequent and occasionally marked.

In some of the embryos the intestinal canal was convoluted throughout. This occurred probably in less than 1 per cent. of the embryos observed, but in a single specimen examined two such were found. The esophagus showed a number of variations. Normally, the first esophageal enlargement was separated from the second by a considerable interval, the two portions being connected by the intermediate intestine. In one specimen, however, the interval was absent, the second expansion appearing at the lower end of the first. In this, as in a few other examples, the cephalic portion of the esophagus showed a double expansion.

In a few instances the embryos presented dark transverse striæ, alternating with lighter areas, the appearance being somewhat like that of voluntary muscle fiber. In these specimens the intestinal canal is usually convoluted, and along the outer and inner borders of the parasite appeared—corresponding to the origin of the dark bands—indentations, which became marked along the inner border when the parasite coiled.

It is probably an appearance similar to this which Strong describes as two longitudinal rows of muscle plates placed along either side of the central canal of the older rhabditiform embryos.

FILARIFORM EMBRYO.

The filariform embryo is about double the length of the younger rhabditiform variety; the capsule or ectodermic layer is thinner and more distinctly outlined than in the rhabditiform variety, and is more perfectly hyaline, containing only a few scattered granules. The inner granular portion is uniform in width. The two expansions seen toward the cephalic end of the rhabditiform embryo have disappeared; the oval sexual gland can not be distinguished; the inner portion is made up of round refractive granules like those of the rhabditiform variety, but larger in size; the intestinal canal ends relatively nearer the tail. The parasite moves very rapidly with a graceful undulatory motion.

CLINICAL HISTORY OF THE DISEASE: ETIOLOGY.

The etiologic factors other than the parasite have not been as yet thoroughly studied. Infection usually takes place by the mouth. It is probable that the parasite is usually introduced in this way as the filariform embryo. Leichtenstern caused infection experimentally in this way by administering filariform embryos to a human subject. Infection has been produced in animals by administering the eggs. The vehicle by which the parasites enter the system is frequently, no doubt, drinking water, but this does not appear to be the only means. Normand during his stay in China drank only water imported from Europe in order to avoid infection, yet he suffered

from a rather severe attack. Fresh vegetables, he thinks, may be a means of conveyance of infection, owing to the Chinese method of fertilization of land by human manure. Probably domestic fowls have a great deal to do with spreading infection, no doubt, through the mediation of fresh vegetables. Fowls are more susceptible to this disease than man, and the infection passes readily from man to animal, and may pass with equal facility from animal to man. Infection through the skin has been demonstrated in rabbits recently under Dr. Stile's supervision. For human infection the infective material must be of comparatively recent origin, as the parasite does not survive long external to the body, even under the most favorable circumstances. The influence of sex in this disease has not been carefully studied. All of the cases which have come under my knowledge in this country have occurred in men. The occurrence of other diseases and of local disturbances of function in the intestine seem to influence, if not the actual infection, at least the manifestation of its results. The frequency with which the disease is associated with uncinariasis, with amebic dysentery, and with other diseases, seems to be more than a coincidence. Climate influences, as already stated, both the frequency of infection and the severity of its results. The more severe forms of the disease are infrequent in temperate countries.

PATHOLOGY.

The pathology of the parasite is mainly taken from Thayer's fatal case and from Strong's later studies. The changes found in the intestine are sufficient to refute the views of those observers who claim that the parasite is innocent to man. The possible ways in which the parasite may produce harm are numerous. Calmette's supposition that the parasite may give rise to substances acting as chemical irritants assumes some probability in the occurrence of a small round-celled infiltration about the ova and parasites, in the crypts of Lieberkuhn. The reflex effects may be a most important pathogenic element; certainly the constant intestinal indigestion, with its attending diarrhea and malnutrition, can not be easily explained by the small amount of inflammation present. The sudden involuntary passages are certainly a reflex nervous phenomenon. We already recognize that the presence of *Oxyuris vermicularis* in the mucous membrane of the rectum is capable of producing in children many reflex disturbances, and it seems reasonable to suppose that the presence of a like irritant in the duodenum and jejunum can produce even more profound effects. Possibly some of the nervous phenomena observed by Sylvestri, such as vertigo, weakness and gastric disturbance occurring in connection with this parasite, may have been of reflex origin.

From Case 1 of Thayer's series Strong prepared sections of the intestine from which he was able to show the injurious influence of the parasite in the intestine. The microscopic appearances were both interesting and instructive. Both embryos, mother worms and eggs were found in the crypts of Lieberkuhn; no eosinophilia was observed about the eggs containing the crypts, but there was present a small round-celled infiltration and karyokinetic figures were observed in the surrounding epithelial cell. The following is a detailed description of the sections prepared by Strong:

Section 1.—Many eggs in various stages of segmentation, some containing embryos, seen generally lying in the bottom of the crypts of Lieberkuhn. In these crypts the epithelium is much compressed and often atrophied. The nucleus lies at the base of the cells, and about it no cell substance can be distinguished, as a rule. Some contain two eggs, and in such cases the epithelial cells seem markedly compressed and atrophied. About the crypts which contain eggs, particularly when they contain eggs which are segmenting or containing embryos not yet hatched, there are a few round cells about the crypt . . . In several sections where the egg has burst and the embryo escaped the epithelium of one side of the crypt has disappeared. About the crypt there is some proliferation, as is indicated by the karyokinetic figures seen in the nuclei of the surrounding epithelial cells . . . the underlying solitary follicles are somewhat swollen. In other crypts the egg rests on the basement membrane of the gland, the epithelium having (apparently) disappeared.

Not infrequently what appears (in transverse sections) to be small cysts are seen lying in the walls of the crypt, resting on the basement membrane. Apparently the eggs have disappeared from the crypts, leaving clear areas. There is no apparent infiltration with round cells about these so-called cysts.

Section 2.—Pieces of the adult female cut longitudinally and transversely. Not infrequently portions of the female containing the vulva may be seen just penetrating into the lumen of the crypts, while others are lying longitudinally or cut transversely in the bottom of the crypt. Occasionally slight round-celled infiltration is noted at the bottom of the crypts containing parasites, and the solitary follicles are slightly swollen. . . .

Section 3.—Many of the crypts contain embryos. In these crypts there is generally flattening and atrophy of the epithelial cells . . . the embryos appear to compress the epithelium . . . mitotic figures and small round cells are seen without the crypt. In several sections embryos are apparently bursting out of the crypt and have desquamated epithelial cells lying about them. One section shows an embryo beneath the epithelium of the villus.

Teissier, in 1895, reported a remarkable case, in which the embryos of the *Strongyloides intestinalis* apparently appeared in both the blood and stools. On account of certain differences in his description of the parasite, and in the observations which he made on it, Thayer concludes that he was dealing with a parasite distinct from the strongyloides group. These differences were mainly as follows: (*a*) The finding of sexually differentiated forms in the fresh dejecta, as well as in culture specimens. (*b*) No internal structure could be demonstrated in the embryonic forms seen in the blood and the smaller forms found in the stools. (*c*) But one spicula was noted in the male form.

In addition to these differences, Teissier, in inoculating experiments on frogs, succeeded in producing metastatic foci in the intestine and lungs, which latter contained giant forms.

After discussing these differences, Thayer advances the supposition that the form of parasite with which Teissier was dealing was the *Ascaris nigrovenosa*, which corresponds closely to Teissier's description, especially in the occurrence of giant forms in frogs.

SYMPTOMS.

The symptoms are those of a more or less continuous diarrhea, characterized by periods of remission, which sometimes exceed one or more weeks' duration. The onset is gradual, and it is some days, or even weeks, before the diarrhea is fully established. The presence of the parasite may be attended by no symptoms for an indefinite period, and none may ever present themselves. As the diarrhea becomes fully established, the evidences of intestinal indigestion appear; certain articles of food will not be digested or absorbed in the intestinal canal. Reflex gastric disturbances may occur; there is occasional heaviness and eructations and slight nausea; vomiting occurs as a symptom in some cases; usually only the severer ones. During the height of the attack the move-

ments increase from twelve to fifteen, or twenty-five per day.

A striking characteristic of the diarrhea is the absence of pain, tenesmus, or any violent depression, such as occurs in other intestinal diseases attended by frequent and copious discharges. Mucus occasionally occurs in the stools, but is always small in amount; in a few cases a trace of blood is present at the onset. The diarrhea may suddenly assume a dysenteric or choleriform character, with purging, vomiting, cyanosis and collapse. This is in many instances due to the concurrent dysentery, to which persons suffering from this disease have a marked predisposition.

Another striking feature is the absence of any elevation of temperature in uncomplicated cases. With the onset of intercurrent disease, and with advanced malnutrition, an elevation of temperature may be present, but with patients otherwise healthy the temperature curve remains uniform during the most severe attacks. In the case observed in the University Hospital the temperature curve showed remarkably few fluctuations, never rising above 99 F. during the patient's stay of nearly six weeks in the hospital. On several occasions of acute exacerbation where the bowel movements exceeded fifteen daily, the temperature did not rise one-half of a degree.

Owing to the intestinal indigestion and consequent malassimilation, there is progressive loss of weight during the acute periods; sweating is an occasional symptom, and a slight reflex cough is occasionally noted. In severe cases emaciation is advanced, there is great debility and weakness, and an intercurrent dysentery or other acute disease proves fatal. A striking and troublesome symptom not infrequently observed is incontinence of the bowel; this occurs most often during the night, but may occur suddenly in the day time. The desire to evacuate the bowels is sudden and almost irresistible. The tongue is usually clean and moist and the breath free from odor; there is no pain in the stomach, but occasionally some intestinal griping. The appetite is apt to be good, except in severe cases accompanied by nausea. The skin and eyes are usually clear, though the latter are occasionally subicteroid. Nervous symptoms are infrequent, but have been reported in a few cases. The symptoms observed were dizziness and vertigo with loss of appetite, weakness and slight nausea.

The blood changes are not usually marked; slight anemia is present, never approaching the degree observed in ankylostomiasis. Eosinophilia is probably not a symptom of uncomplicated cases; there is no leucocytosis. The stools present the ordinary appearance of intestinal indigestion, and contain undigested food. On microscopic examination there are present starch, granules and oil globules, together with pus, epithelial and red blood cells. After the disease is established the stools do not regain their normal consistence, but vary from a pasty to a fluid state. As would naturally be supposed, indigestible articles increase the diarrhea; corn especially, and occasionally beer, appear to excite a relapse.

DIAGNOSIS.

Diagnosis depends on examination of stools. The clinical features, however, are very suggestive; the occurrence of considerable intervals of remission, during which the patient largely regains his previous health, the absence of pain or any elevation of temperature, and the absence of blood or mucus in the stools in appreciable amounts, are all symptoms individual to this disease. Incontinence of the bowel, if present, is extremely characteristic. In practice, amebic dysentery will be most frequently confused with this disease, as they also run a very intermittent course, and the elevation of temperature may be slight or absent. An examination of the blood in these cases will at once clear up the diagnosis. The leucocytosis seen in amebic dysentery is absent in infections with the strongyloides, and it is not likely that other chronic diarrheas and dysenteries will be confused with this disease, by those who keep the features already mentioned in mind.

TREATMENT.

The treatment consists in light diet, rest and tonics, with occasional heavy doses of thymol or Felix mass, followed by a purge. The milder cases are easily controlled by treatment, the most severe difficult to influence in any way. While the patient may be relieved of nearly all unpleasant symptoms, the complete eradication of the parasite is a matter of some difficulty. I know of no case, at present, where this has been accomplished. No medication will cause the parthenogenetic mother worm to appear in the stool, and until this occurs treatment can not be considered successful.

After the patient has been relieved of his more acute symptoms by ordinary measures of rest and diet, thymol may be given on an empty stomach, preferably in the morning; 10 to 12 grains given in capsules every five minutes for an hour, and following this, a saline, watching carefully for any symptoms of depression or collapse induced by the thymol; male fern may be used in place of thymol, given in a dram dose, followed one hour later by another dram. Between the periods of more active medication tincture of ferric chlorid may be given as a tonic. Gin has also been recommended.

I wish to recommend at this time, on purely theoretical grounds, the adoption of a more radical procedure in the treatment of this disease. I think we are justified in these cases in endeavoring to effect a radical cure at the cost of considerable patience, or even risk to the patient. It is true that we can easily control the majority of cases met with in this country by appropriate treatment, but, aside from the danger to life, there are other considerations which we have to meet. The disease imposes considerable disability on patients suffering from it, and it falls especially hard on those who earn their living by manual labor, as the frequent discharges interfere with any continuous employment. Again, in debilitated persons, especially the tuberculous, there is considerable indirect risk of life. Intestinal malassimilation is always a serious feature in this disease, and may result in developing a case previously latent, or in converting the chronic into the acute form. I would advocate treatment along several experimental lines, having for their object to render the habitat of the parasite unfavorable to development. The parasite is not especially robust, and can be destroyed external to the body by trifling untoward circumstances.

The presence of air, a moderate temperature and the power of free motion in a fluid or semi-fluid nutritive medium is essential to the life of the parasite. A moderate degree of heat is sufficient to destroy it. In the endeavor to influence the parasite unfavorably we can first proceed along the lines of depriving the parasite of air; this we should be able to accomplish, practically, for several days without any unsurpassable difficulty. The method by which we should accomplish this will probably be by means of a primary purge, followed by doses of opium sufficiently heavy to arrest intestinal peristalsis. Rectal alimentation should be used during

this period to further guard against the entrance of air into the intestines. With the intestine empty and collapsed, and its walls in approximation, the small quantity of air remaining will soon be lost. In order to promote the absorption of any residual air, recently heated wood charcoal may be administered with the opium. An endeavor to destroy the parasite by heat may be combined with this method. The administration of very hot fluids continuously by mouth may be combined with the preceding method. The intestine is very tolerant of hot liquids, and the temperature required is not great. In order to avoid the discomfort incident to swallowing very hot liquids, they may be administered by a stomach tube combined with some agent to facilitate the rapid passage of the fluids into the duodenum. These two methods may be combined in a procedure such as given below:

After a twenty-four hours' fast the patient is given two drams mag. sulph. in two pints of very hot water, one drop of croton oil is added to insure prompt passage from the stomach. The solution of mag. sulph. may be repeated again in an hour without the croton oil. After the patient has been thoroughly purged, opium is given by the mouth, combined with powdered charcoal, after which it is administered by rectum as long as may be considered necessary. Arresting of all movements for a week should be all that is necessary in the usual case. At the end of the stated period the solution of mag. sulph. is administered in the same manner.

PROGNOSIS.

The prognosis of the disease has already been discussed under the treatment.

I wish in conclusion to express my thanks to Dr. Thayer and Dr. Strong for the use of previous reports on this subject, both of whom I have freely quoted, and from the former of whom I have largely modeled my report. Also to Dr. Atkinson for valuable advice and assistance in the case.

DISCUSSION.

Dr. Charles Wardell Stiles, Washington, D. C.—This parasite of Cochin China diarrhea must be more common in this country than is commonly supposed. It is not only found about Baltimore, but four cases are reported from Washington and three cases from California. The life conditions necessary for this parasite are much the same as are necessary for the uncinaria. We can expect this nematode to correspond more or less generally to the geographic distribution of uncinaria.

With regard to the diagnosis, there are one or two pitfalls. We may find small worms and make the mistake of thinking that we have to deal with Cochin China diarrhea. Mistakes of this kind have been made by European and Asiatic physicians when they state that uncinaria runs through the same double cycle of development shown by strongyloides. Looss reported that he found in the feces rhabditiform embryos which were scarcely to be distinguished from the diarrhea worm. Various rhabditiform embryos are not uncommon in water and vinegar, but which have no connection with strongyloides, yet they may be found in the stools. If you wish to make a diagnosis of Cochin China diarrhea the simplest way is to find several rhabditiform worms in the feces; then a few of them should be raised to the free adult stage.

Another pitfall is likely to occur in the southeastern states. Occasionally the embryo of the American hookworm develops while the egg is still in the uterus of the female; and occasionally we may find in the feces of hookworm patients eggs with fully-developed rhabditiform embryos. If the egg shell is broken the rhabditiform embryos can then be distinguished from the strongyloides embryos only with difficulty and with the most careful examination.

Another pitfall is this: The pin worm (oxyuris) is viviparous, and here the embryos simulate the strongyloides embryos. In the tropics and in the Philippines strongyloides is a very common parasite, and we are likely to find cases of Cochin China diarrhea in almost any part of the country where we are dealing with soldiers who have served in the tropics. I do not know what treatment we are going to use. The results with thymol are not at all satisfactory.

Dr. Allen J. Smith, Galveston, Texas—This worm, I am satisfied, is a more common human parasite in the southern part of the United States than is at present realized. I have personally encountered examples of the embryo a number of times in the stools of patients from Galveston, but passed it by as a matter of interest rather than of importance, accepting in this idea the statements usually made in the text-books as to the rôle of this parasite in pathology. I must here (and I do so without hesitation) acknowledge that it was due to this mental attitude of mine that Dr. John T. Moore, Galveston, refrained from publishing an instance of the presence of the embryonic worms met in one of his patients a number of months ago, at a time when such publication would have ranked high in order of priority of record of the parasite in this country. I had seen the worms before; had not recognized in the cases presenting them any definite clinical features referable to these zoöparasites; was aware that the original idea that they were the cause of Cochin China diarrhea had been abandoned and that writers generally were agreed that they were of little or no importance in pathogenesis. Under this impression I spoke of the matter lightly when Dr. Moore brought to the laboratory of pathology in the University of Texas his specimens for identification; because of which Dr. Moore refrained from reporting the case until some months later, when his interest was again aroused by Dr. Thayer's excellent discussion of the same parasite in the *Journal of Experimental Medicine*. Since Dr. Moore's case two others have been brought to my notice from the wards of Sealy Hospital.

On such reasons I would base my confidence that the parasite is probably frequent in the southern tier of states of this country. In the cases which I have known the discovery of the worms has been in a general way accidental, and there has been nothing to make them seem of actual clinical importance. In one of these cases, however, at the time of the examination, there was a decided diarrhea, in which possibly the strongyloides may have had some influence; but the parasites persisted after the subsidence of the diarrhea—and aside from this individual circumstance I have had no reason to think of the anguillula as of any pathogenic significance.

Dr. A. P. Ohlmacher, Gallipolis, Ohio—Some five months ago my interest in this subject was aroused by the discovery of *Strongyloides stercoralis* in an epileptic idiot, 16 years of age, one of the inmates of the Ohio Hospital for Epileptics. He was a native of Cleveland, Ohio, where he had lived at home until admitted to our institution, Jan. 7, 1902. There was no history of diarrhea before admission. His death occurred Nov. 23, 1902, from exhaustion. A diarrhea appeared three months previously, and three days before death the stools were blood-stained. He was confined in one of the closed wards. I examined the contents of the large intestine during the progress of the autopsy, finding the strongyloides; and subsequent search through the intestinal tract exhibited the worms from the pylorus to the anus. Both the adult female worm, eggs and developing embryos were found. My tentative diagnosis of strongyloides was confirmed by Dr. Chas. Wardell Stiles of Washington, who kindly examined some of the material from this case. This additional case, the first in the middle west of the United States, seems to emphasize the point made by Dr. Stiles and others in the present discussion—that the worm of Cochin China diarrhea is not a rare parasite in this country.

Dr. J. T. Moore, Galveston, Texas—My first case was discovered in August, 1901, the patient appearing at the outdoor clinic of the John Sealy Hospital complaining of severe diarrhea, with cramps in the abdomen. He was rather nervous and slightly anemic. He was a mulatto. He had served in

the Spanish war in Cuba. The stools were examined and the parasite of *Strongyloides intestinalis* was found. The specimen was submitted to Dr. Smith, who told me it was *Strongyloides intestinalis.* I remembered hearing of Dr. Thayer's case spoken of in Washington, I believe, at the American Congress of Physicians and Surgeons. Dr. Thayer kindly sent me a monograph of his cases. I reported my case to the medical society in June, 1902, and it is now in the hands of the American Medicine Publishing Company, the manuscript having been corrected. Recently I sent Dr. Price a synopsis of the case. I have now two other cases to be reported that I have since seen in the medical wards of Sealy Hospital. This parasite is, I believe, of common occurrence in Galveston and vicinity. I recently had another case under observation in which I saw both the rhabditiform and filariform parasites. I have never been able to secure the eggs of the strongyloides, although I have made cultures several times. I have seen many cases of uncinariasis.

THE SURGICAL TREATMENT OF UNDESCENDED TESTICLE.

A FURTHER CONTRIBUTION.*

ARTHUR DEAN BEVAN, M.D.
Professor of Surgery, Rush Medical College, University of Chicago, and Surgeon of the Presbyterian Hospital.
CHICAGO.

At the Columbus meeting of the American Medical Association I read, before the Section on Surgery and Anatomy, a paper entitled "Operation for Undescended Testicle and Congenital Inguinal Hernia," published in THE JOURNAL of the A. M. A., Sept. 23, 1899. Since that time I have had the opportunity of operating on a further series of cases, representing practically all the varieties of this malformation and have made some improvements, made necessary by difficulties occasionally met, which make operative reduction of the misplaced testicle possible in almost all cases; and places, I believe, the operation in a position where it should be accepted as a standard surgical procedure.

A further reason for again presenting this subject is the fact that a number of my colleagues have informed me that they have had difficulty in understanding and in carrying out the operation which I recommended, and I have felt that a series of plates illustrating the various steps of the procedure might make the matter clearer. The plates which I submit are sketches from life of the various steps of the operation.

I am inclined to believe that where an operator fails to succeed it will be due to the lack of that anatomic knowledge which he must possess to enable him to unravel the shortened structures, and at a stroke of the knife and in half an hour imitate the normal descent of the testicle. I regard the operation as one of the most interesting examples of applied anatomy.

It will not be necessary here to review the normal descent of the testicle. Figure 1 shows graphically this descent: A. The first position of the testicle below the kidney and behind the peritoneum. B. Passing through the canal. C. In the scrotum, with open vaginal process, so that the general peritoneal cavity and the future tunica vaginalis are still continuous. D. The vaginal process obliterated, the general peritoneal cavity shut off from the tunica vaginalis. There is one fact in connection with the descent of the testicle which is of importance in the operative reduction and which is generally not known or misunderstood, and that is that long before the testicle descends through the canal the vaginal process of peritoneum has preceded it, lying in front of the gubernaculum testis and reaching into the scrotum. The idea so prevalent among medical men that the testicle drags down a process of peritoneum in its descent

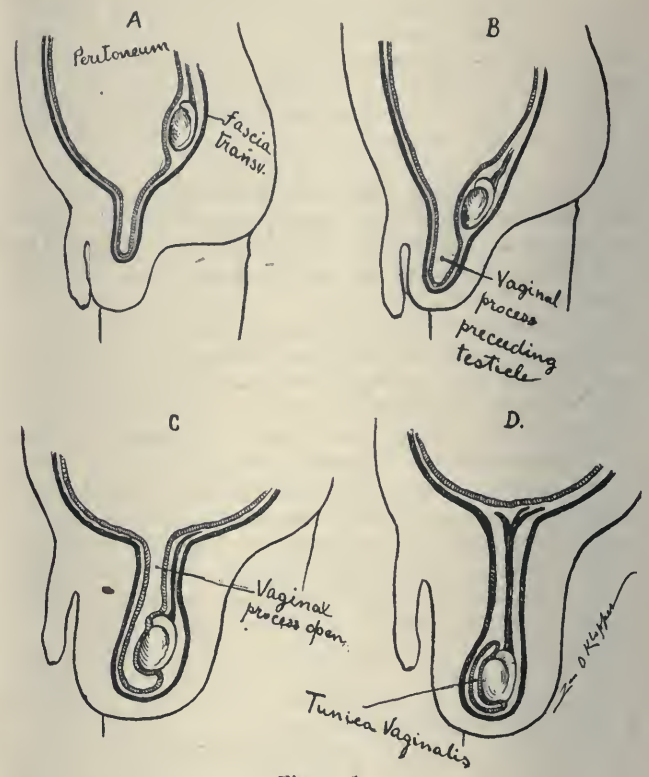

Figure 1.

is an error. I have found in all my cases, even where the testicle is well within the abdomen, a large sac of peritoneum, passing through the canal, occupying the space

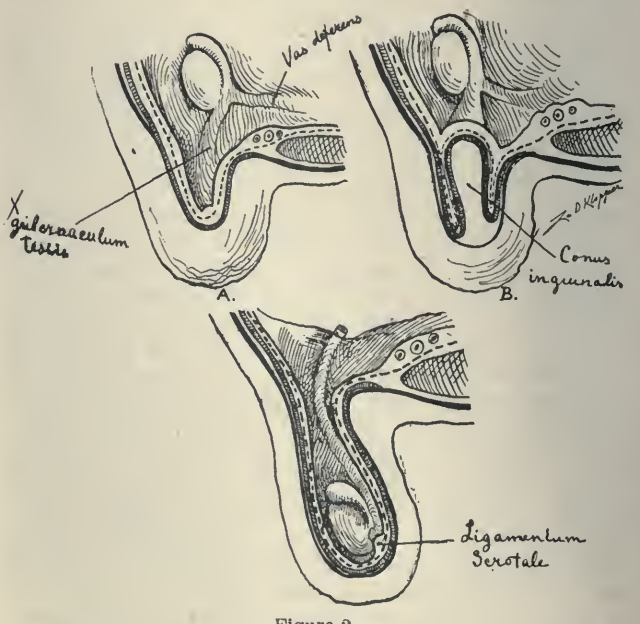

Figure 2.

in front of the external ring and passing down toward or into the scrotum.

Figure 2 shows graphically the descent of the testicle in three stages, and shows the process of peritoneum and the gubernaculum testis preceding the testicle in the scrotum.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

For clinical purposes, we may divide the malformations in connection with the descent of the testicle into:

1. Simple failure of the vaginal process to close, giving us the picture of congenital inguinal hernia, or at least a potential hernia.

2. Incomplete closure with such conditions as hydrocele of the cord.

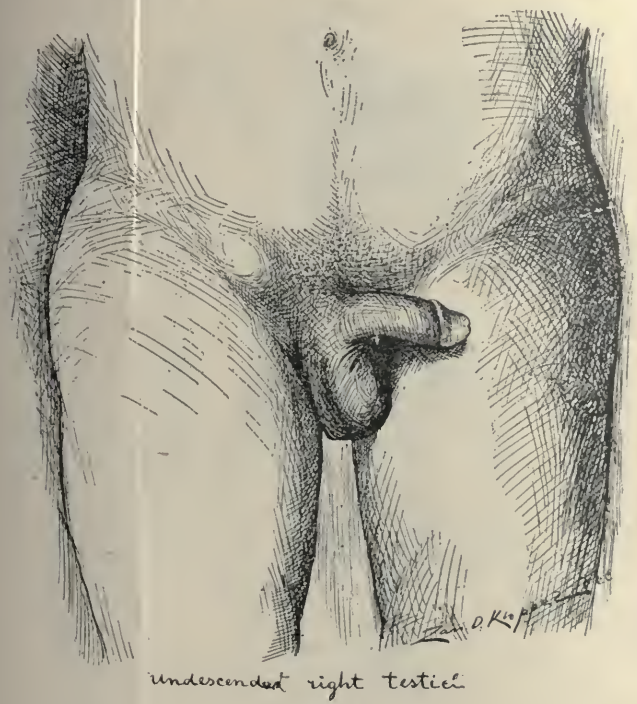

Figure 3.

3. Undescended testis which presents four types: (a) in the abdomen, in about its original position; (b) at the internal ring; (c) in the canal; (d) external to the external ring.

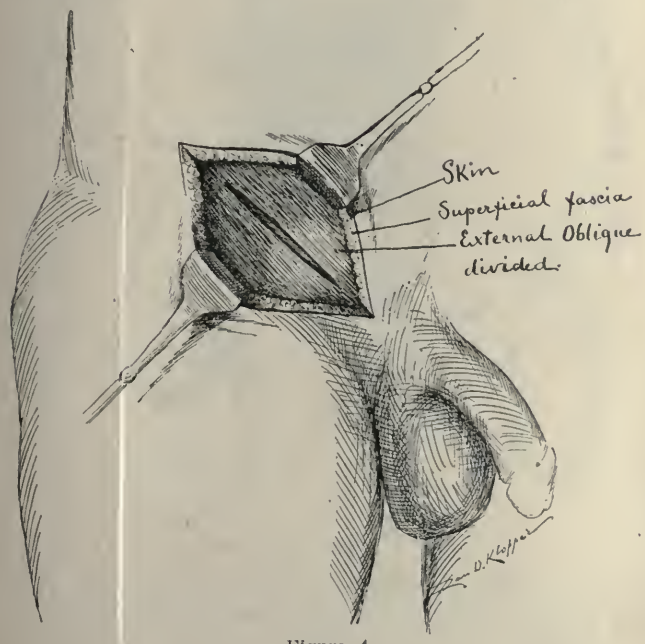

Figure 4.

4. Misplaced testicle. (a) in the perineum; (b) on the thigh below Poupart's ligament.

Undescended testicle occurs in at least 1 in 500, as shown by the statistics of the Austrian army, obtained from an examination of recruits. The malformation is a serious one, as it brings with it both mental and physical distress and it deserves more consideration from the medical profession than has been given to it. Even to-day almost no mention of the condition is made in our standard text-books on surgery, and the idea is generally prevalent among medical men that nothing can be done for the cure of the conditions, except removal of the testicle, if it causes trouble.

To-day, I believe the rule should be to operate and transplant to its normal position in the scrotum every

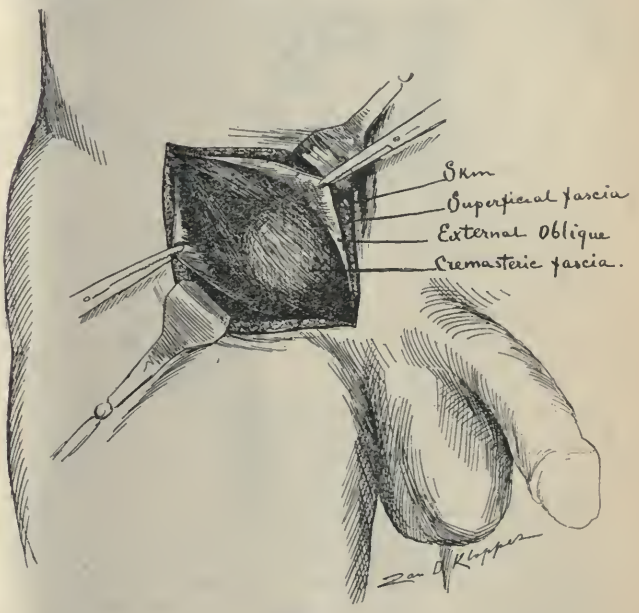

Figure 5.

undescended testicle which can be palpated. Those which can not be palpated should be operated on if they give rise to symptoms, or are complicated with hernia. Those which can not be palpated and do not give rise to

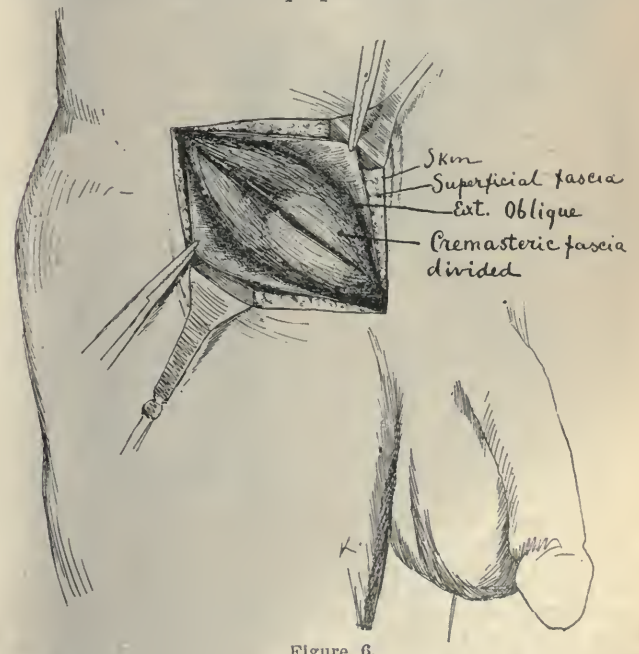

Figure 6.

physical distress, should be operated on and placed in the scrotum, if the malformation is the cause of mental distress to the patient. There are but few cases of undescended testicle where an operation is not indicated.

The dangers and discomforts of the condition of undescended testicle are much greater than those of the ordinary inguinal hernia and call more urgently for operative relief. These dangers are, briefly, (1) the actual or potential hernia which is always present; (2) greater liability to, and greater danger from, inflamma-

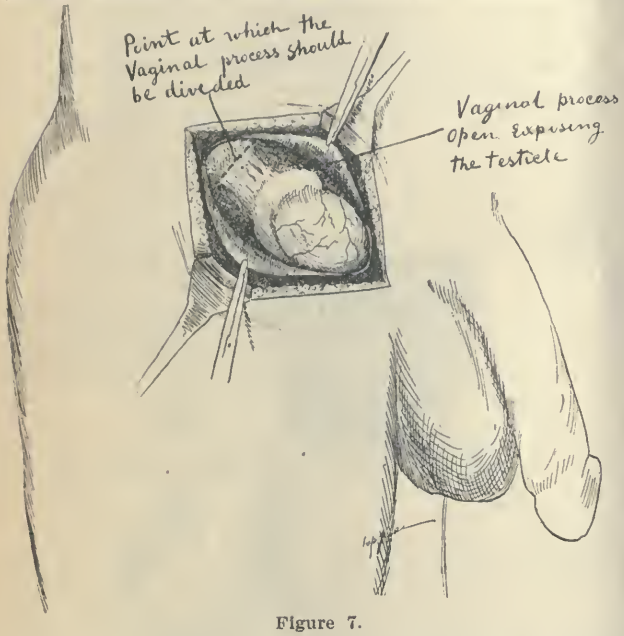

Figure 7.

tion of the testicle in its abnormal position; (3) injury to the organ from its exposed position, both external injury and injury from muscular contraction, such as coughing, lifting, etc.; (4) the greater danger of malignant degeneration (there can be little doubt that these

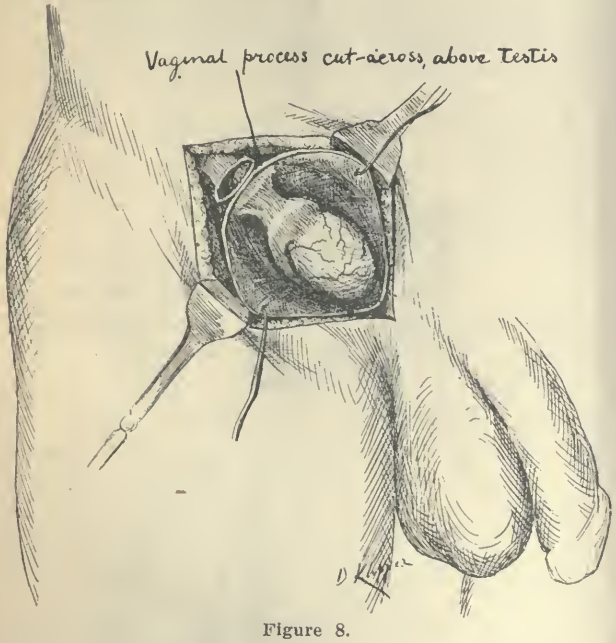

Figure 8.

undescended testicles are more often the seat of malignant disease than are normal testicles); (5) mental distress, due to the existence of the condition. This is an important factor in many cases. We do not hesitate to give our patients, suffering from hernia, the benefits of an operation for radical cure, and we should not refuse the cryptorchid the benefits of a surgical procedure, which, if properly performed, is as safe and as sure as a Bassini hernia operation and more urgently called for.

The first work of value in this line was done in 1881 by Max Schüller, and reported in this country in the *Annals of Anatomy and Surgery*. Schüller recognized the vaginal process of peritoneum as the chief factor which prevented the drawing of the testicle down into the scrotum and the factor which drew the testicle back

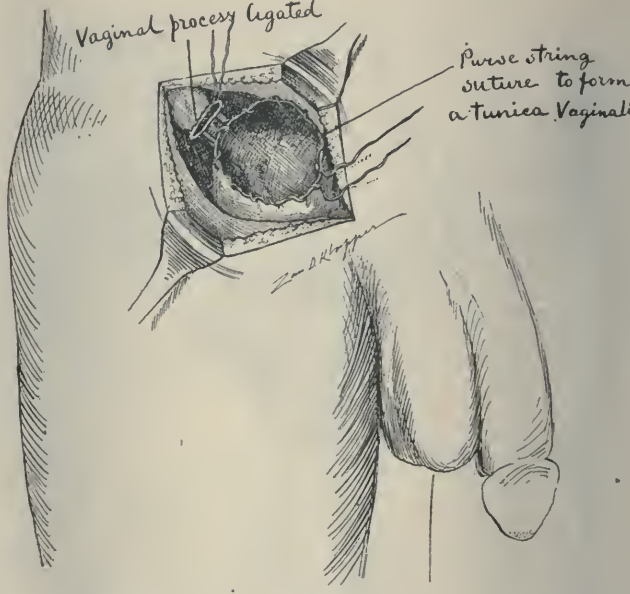

Figure 9.

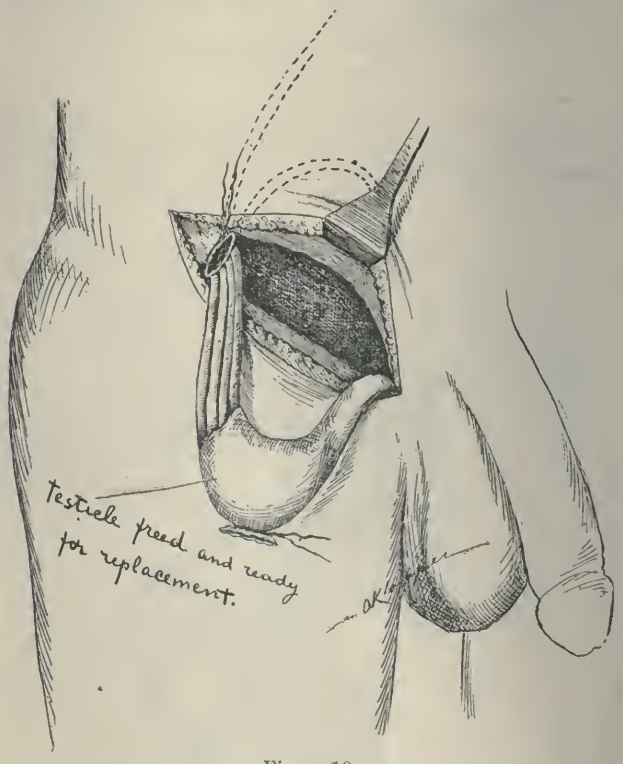

Figure 10.

into its old position, after operation. He advocated division of this vaginal process and stitching the testicle into the scrotum.

Schüller's work was a distinct step in advance, but his operation did not go far enough and has but a limited field. The operation which I have developed meets, I think, the indications better and has a much wider field of usefulness. I have developed the operation so that testicles well within the abdomen, which have never

been palpable, can be brought down and retained in the scrotum. Before describing the technic, which is the special purpose of this paper, I desire to say a word in regard to the age of selection. At what period of life, if we can choose, should these patients be operated on?

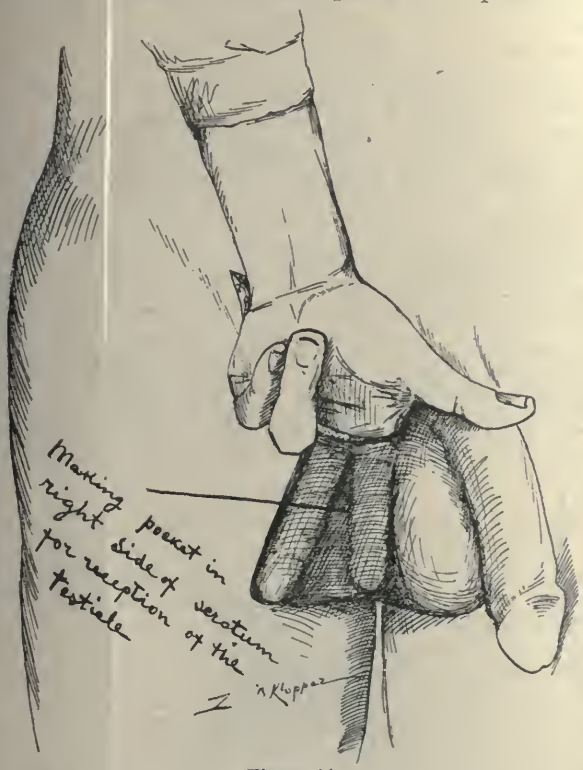

Figure 11.

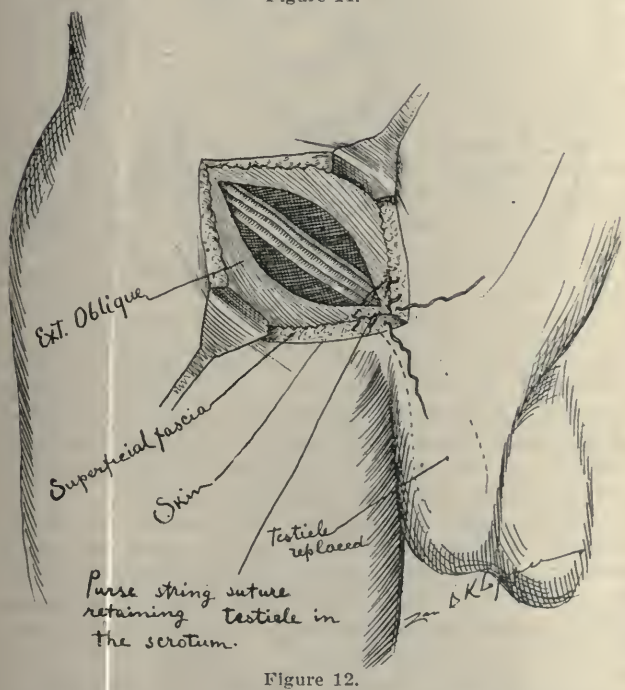

Figure 12.

In my first paper, I advocated waiting until after puberty, on the ground that some of these testicles descended during puberty and the malformation was cured sometimes even without an accompanying hernia. I have changed my opinion decidedly on this point, because I believe that this descent at puberty is a rare occurrence, at least, that it happens in but a small per cent. of the cases, and again, I believe that it would be far better to have the testicle in the scrotum when the changes incident to puberty take place. I now, therefore, advocate the performance of the operation before puberty, when possible, I think best, between 6 and 12 years of age.

DESCRIPTION OF THE OPERATION.

In operating on undescended testicle, when the organ is palpable, as in Figure 3, that is, in the canal or external to the external ring, the following technic should be pursued:

Make an incision three inches long over the canal. This should never involve the scrotum, or extend farther inward or downward than the external ring. This incision should divide skin and superficial fascia and the external oblique over the inguinal canal (Fig. 4).

The divided aponeurosis of the external oblique is drawn to each side and the cremasteric fascia is exposed (Fig. 5).

The cremasteric fascia and the thin underlying transversalis fascia is freely divided parallel with the canal (Fig. 6).

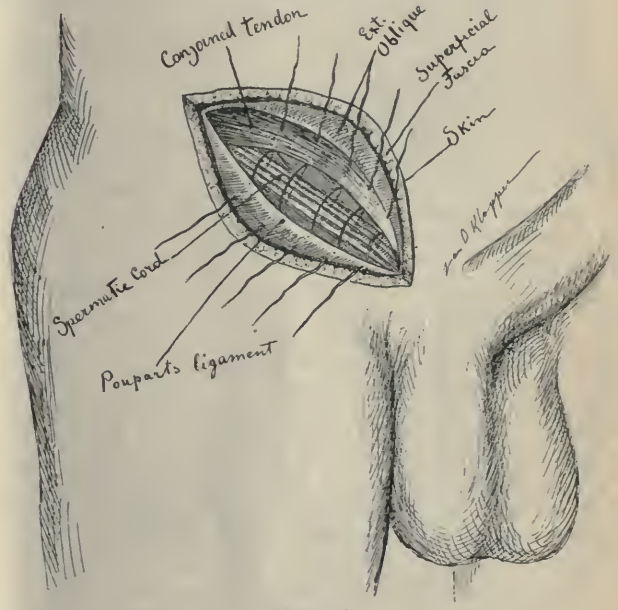

Figure 13.

This exposes the large peritoneal sac containing the testicle and continuous with the general peritoneal cavity. This sac is opened and the testicle exposed to view (Fig. 7). Frequently a projection of the omentum is found in the sac.

It is not necessary to make as large an opening into the sac as is shown in Figure 7. The peritoneum is then cut across at the point shown in Figure 7, and is carefully separated from the cord which lies beneath.

Figure 8 shows the vaginal process of peritoneum, cut across above the testicle. The vaginal process is then ligated, as in the neck of the hernia sac in a hernia operation, care being taken to ligate well up at the internal ring. That portion of the peritoneal sac in contact with the testicle is closed with a purse-string suture, and thus forms a tunica vaginalis for the testicle (Fig. 9). The testicle is now lifted out of its bed, and the cord is gently pulled on, so as to lengthen it as much as possible. In doing this, shortened bands of connective tissue will be seen as tense bands in the cord, and these should be torn across with tissue forceps. The cord should thus be stripped of all the surrounding fascia, leaving nothing but the vessels and the vas deferens. When this has been accomplished the spermatic vessels

and the vas, which lies behind the posterior layer of peritoneum of the abdominal cavity, should be separated from the peritoneum by careful blunt dissection, with the finger introduced into the abdominal cavity. The spermatic vessels will be found passing upward and inward, and the vas downward and inward from the internal ring, and this divergence can be plainly seen. The cord should be so lengthened by these maneuvers that the testicle can be layed on the thigh three or four inches below Poupart's ligament (Fig. 10).

With blunt dissection with the fingers, a large pocket should be made in the scrotum for the reception of the testicle (Fig. 11), and the testicle dropped into it, where it should remain without tension on the cord. A purse-string suture should now be placed at the neck of the scrotum to retain the testicle in position. This suture should pass through the superficial fascia and the external oblique on both sides of the incision; that is, both the internal and external pillars of the external ring, and above the cord. When this suture is tied, the testicle is securely retained in its scrotal pocket (Fig. 12). The incision is then closed, as in a Bassini operation, except that we do not transplant the cord; that is, we bring the conjoined tendon and Poupart's together above the cord (Fig. 13). We then suture the incision in the external oblique with continuous suture (Fig. 14), and, lastly, close the external wound. I have employed formalin catgut for the buried sutures and horsehair for the skin sutures. A fairly firm, not uncomfortable, compress over the canal, retained with spica bandage, completes the operation. The horsehair sutures are removed on the tenth day, the patient allowed on his feet on the fourteenth day.

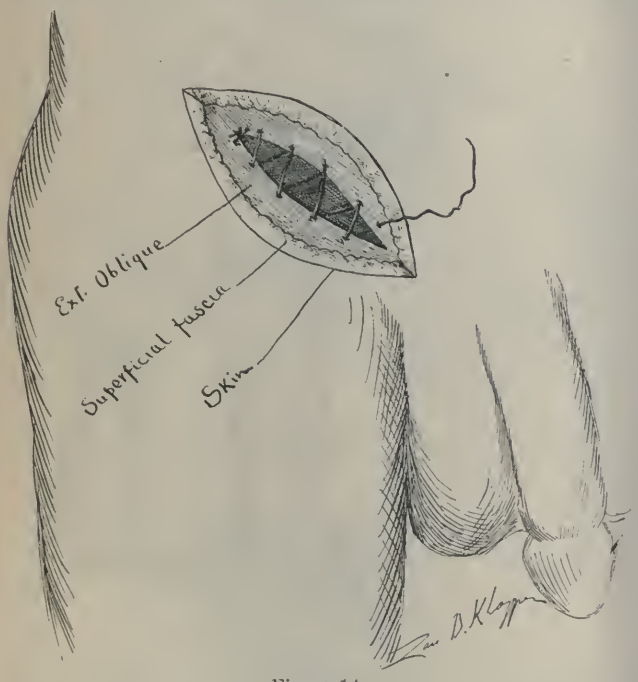

Figure 14.

The technic I have described will answer in a large majority of cases, but I have found by experience that in operating on cases in which the testicles are not palpable, and are well within the abdomen, and in some few cases when the testicles are palpable, that I could not, by the method described above, free the testicle sufficiently to bring it into the scrotal pocket, without tension. In analyzing the facts in these cases, I found that the tense structure which prevented reduction were the spermatic vessels, and not the vas. The spermatic vessels run in almost a straight line from the internal ring to the abdominal aorta and the ascending vena cava and renal vein. The vas, on the other hand, makes a long sweeping curve in its course from the internal ring to the base of the bladder. The artery of the vas accompanies it and follows this same curve. The vas is the essential organ in the spermatic cord.

The question which confronted me in some of my difficult cases was whether the spermatic vessels were structures essential to the integrity of the testicle, or whether they could be safely sacrificed, in those cases in which the testicle could not be sufficiently freed without dividing them.

Reasoning from a clinical experience of more than a hundred varicocele operations in which I had removed all of the structures of the cord, with the exception of the vas and its vessels, and had never seen gangrene of the testicle, or any apparent interference with its nutrition, I concluded that the spermatic vessels could be safely sacrificed in those cases where it is necessary to divide them in order to bring the testicle well down in the scrotum. I have, therefore, in a number of cases ligated the spermatic vessels at two points and divided between, as shown in Figure 15, and have had no evidence of interference with nutrition; in fact, these have been among my most successful cases, from the standpoint of clean and rapid recovery.

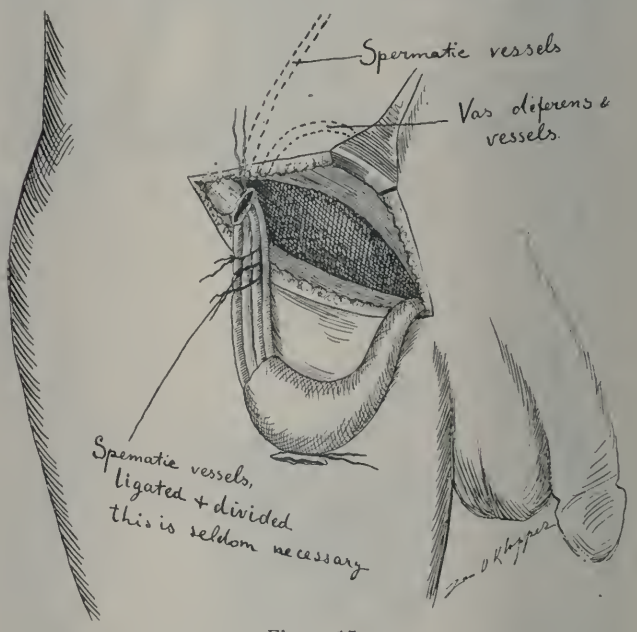

Figure 15.

After my first operation of this kind I found that J. Griffith,[1] writing on the effects on the testes of ligature of the spermatic artery and spermatic veins, and of both artery and veins, had demonstrated that these vessels could be sacrificed without any permanent interference with the function of the organ.

The explanation is this: The testicle is supplied by two arteries, the spermatic from the aorta, and the artery of the vas from the inferior or middle vesical. These anastomose freely; neither are terminal arteries, and either can be sacrificed without endangering the vitality of the testicle.

Since adopting this seemingly radical, and yet perfectly safe, sacrifice of the spermatic vessels, I have had no difficulty in bringing the testicle down into the scro-

1. Journal of Anatomy and Physiology, vol. xxx, p. 81, 1895.

tum, even in cases where it was well within the abdominal cavity, and where it had to be hooked out of the abdominal cavity and held with some tension to keep it out beyond the internal ring, until the shortened structures were divided.

I desire to urge the general adoption of operative treatment for undescended testicle. By the operation the testicle can be placed in its normal position in the scrotum, where it certainly has a better chance of developing into a normal organ than it has if it is allowed to remain in its abnormal position. At the same time, the patient is cured of the actual or potential hernia, which is always present, and is freed from the dangers and discomforts which result from the malformation, and this can be accomplished by an operation which is as safe and as sure as the operations for radical cure of hernia, and, to my mind, is much more urgently called for.

The operation requires of the operator a very clear conception of the normal anatomy of the region and the abnormal anatomy of the malformation, but otherwise presents no greater difficulty than does a Bassini hernia operation.

DISCUSSION.

DR. W. T. ECKLEY, Chicago—I shall speak on four points: (1) The diaphragmatic ligament of the primitive kidney; (2) the gubernaculum; (3) the inguinal ligament of the primitive kidney; (4) the probable factors concerned in cryptorchism. At an early period the mesonephros and indifferent sexual gland are in a retroperitoneal bed of mesodermic tissue. That portion of the mesodermic tissue cephalad of the sexual gland is called the diaphragmatic ligament of the primitive kidney; the portion caudad of the gland is the inguinal ligament; while the part corresponding to the gland becomes the mesorchium or mesovarium, according to sex. With the disappearance of the primitive kidney, the diaphragmatic ligament atrophies. The inguinal ligament develops the gubernaculum. The gubernaculum is attached, cephalad, to the sexual gland, and its inverting peritoneum, caudad, to the inguinal region and bottom of the scrotum. By traction it produces a test-tube-like processus vaginalis—a preformed structure for the reception of the testicle. The emphasis placed on the occurrence, together with cases reported by the essayist of congenital hernia and cryptorchism in the same individual, seem to clear up a hitherto controverted anatomic question, viz., whether the testicle and processus vaginalis descend at the same time. In one case at least I can corroborate Dr. Bevan's opinion that the processus vaginalis is preformed for the reception of the testicle. By a strange hypervivacity the gubernaculum may reduce to processes of peritoneum, one of which favors the occurrence of infantile hernia.

Two factors figure conspicuously in the causation of cryptorchism: (1) the spermatic vessels; (2) an unobliterated diaphragmatic ligament of the primitive kidney.

DR. CARL WAGNER, Chicago—It is not only from a psychologic standpoint of view that these cases of undescended testicle appeal for relief, but also from the anatomic and pathologic points of view, for there may be serious dangers which may be obviated through such surgical devices as Dr. Bevan's. In this connection I wish to report a case of undescended testicle, in which this condition is responsible for the loss of one testicle. It took place in a young boy, who fell about fifteen feet. He complained of severe pain in the left inguinal region. I saw the boy the second day after the accident and found a swelling the size of a small walnut in a region corresponding to the seat of the internal ring. Further examination disclosed the fact that there were no testicles contained in the scrotum. Thus I concluded that the swelling contained the undescended testicle which through the force of the fall had been thrown into the inguinal canal. On opening up, I found the testicle tightly encircled by the pillars of the internal ring, around its middle, and gangrenous. It became necessary to incise the internal ring upward in order to free and ligate the testicle off, which could not be moved downward the least bit.

I feel very much encouraged by this paper to operate on undescended testicles, and thus prevent dangers of similar character.

DR. WILLARD BARTLETT, St. Louis—There is a certain pathologic condition which must guide us as to the time at which this operation should be performed. What Dr. Bevan has said about doing the operation early is undoubtedly true. The undescended testicle is of value to us only to facilitate the development of the child. It is known that the boy who possesses two undescended testicles develops into the manly type, whereas the infant that is robbed of two normal testicles develops into an effeminate type. Knowing as we do, then, that the undescended testicles are of value only to further the development of the child, and knowing as we do that the infant develops into the girl type if the testicles are removed, it would seem that they should not be removed in the early years. On the other hand, the danger of malignant disease from undescended testicles after they are reduced is just the same as though they had been left in the abdomen. Consequently the logical conclusion must be drawn that such a testicle must be removed entirely, if you do anything to it after about the age of 18 or 20 years, whereas, as Dr. Bevan has said, the psychologic considerations would demand that they be brought down in the scrotum, if anything be done with them early.

DR. A. J. OCHSNER, Chicago—This paper is of very great importance, because up to the time at which Dr. Bevan first wrote on this subject the general tendency was to substitute the removal of the organ for its replacement. In the former paper Dr. Bevan emphasized the fact that the reason why the former attempts at replacement of the testicle had been unsuccessful was because the organ had not been loosened. He showed how the organ was held by a curled-up condition of the tissues of the cord, and that by unfolding these tissues it was possible to place it in the scrotum. Since hearing this paper read at the Cincinnati session of this Association, I have many times performed this operation and, except in the first case, in every instance with perfect satisfaction. In the first case one point made by Dr. Bevan in his original paper had escaped my attention, which I learned later in looking up the paper, namely, that the organ may be almost perfectly loose and still be held by the peritoneum. The tissues of the cord may be relatively loose and yet there may still be a certain degree of tension. Realizing this degree of tension which has been described, I have always performed the Ferguson operation in preference to the Bassini, making use of the principles brought out by Dr. Bevan and, with the exception of the first case, with perfect satisfaction.

DR. WILLIAM L. RODMAN, Philadelphia—It has been my lot to see a great number of cases of this condition, and I feel it is better to incorporate the testicle in the scrotum than it is either to excise it or to leave it in the abdominal cavity, for three reasons: The first is that the patient would, of course, very much rather have the testicle in its normal place, and the moral effect is very much better. Second, the place for the testicle is where it is least likely to undergo any form of malignant disease, and certain it is that all such organs are much more likely to undergo malignant change if left in the abdominal cavity than if they are placed in their normal position. I know some one has denied this, but I think the evidence is absolute that the undescended testicle is prone to undergo degenerative change. The third reason is that the testicle in the inguinal canal can expand and grow and develop in a way that it could not if it remained in the abdomen, and that is the chief reason why these organs are practically without function, and why a person with two undescended testicles is practically impotent. Naturally, there will be a much better chance for the development of the testes if the operation is done early, as Dr. Bevan says, and not after puberty. I think undoubtedly he was correct in changing his position and saying that these operations should be done before puberty. The last case that I operated on was a child about 8 or 10 years old. He was the son of a

physician living in New Jersey. He had become very much concerned about the future of the child, and rightly, I think, insisted on the operation being done early. In one case which occurred in a young man I was able to bring both testes down and anchor them in the scrotum in the way indicated by Dr. Bevan. I am glad to say that the results have been very good, although I believe the testicle, even if brought down into the inguinal canal, will never become functionally active.

DR. ARTHUR DEAN BEVAN, Chicago—In regard to the question raised by the last speaker, I think that we must always be guided by the conditions which are present. The operation is performed, of course, with the idea of giving relief to the individuals who have undescended testicles. Of course, these cases are almost always complicated by hernia, and the point I wanted especially to make is that by this method we have only to bring the testicle down and do not have to apply any tension. My experience has been rather limited in this work, about twenty cases, but I have not seen more than one where we could not bring the testicle down without any tension.

APOPLEXY.

T. B. GREENLEY, M.D.
MEADOW LAWN, KY.

On account of some peculiarities in the way of symptoms, I report a case of apoplexy.

A female, aged 81, was stricken Sept. 10, 1902, with all the symptoms of cerebral hemorrhage. She was unconscious and paralyzed, which condition continued nearly twenty-four hours, when consciousness returned. In a short time she could move her left foot, and we soon discovered that she had hemiplegia of the right side.

In a short time she could use her left extremities, so that she could feed herself, lying on her right side. She remained in bed about two months, when we allowed her to sit up a few hours at a time in the morning and afternoon.

In three months she was able to walk with a little assistance. She now ate her meals at the table, and sat up nearly all day. Her appetite and digestion were nearly as good as before she was taken sick.

At first we had no hope of her recovery on account of her advanced age and the severity of the attack, but now she was so much improved we began to entertain great hopes of her final recovery.

She could not use her right hand in feeding herself, but could stoop down and pick up light things, such as a paper, requiring but little grip.

In about four months from the time of attack, she could pull herself up and walk alone through the rooms and hall, which she frequently did during the day for exercise.

She was perfectly conscious of her surroundings and recognized friends who called to see her; but she never recovered the ability to command language to express her feelings, or to converse with her friends. She endeavored to talk, but could speak very few intelligible words. This is one of the rare symptoms attending apoplexy.

There is frequently inability to talk immediately after an attack due to paralysis, but I have not met with a case where this condition existed after regaining the use of the muscles of the tongue, etc. One singularity in her case attended this condition, which was, if you requested her to count, she could do so up to any number, and enunciate the words distinctly. She could also repeat the letters of the alphabet very distinctly. This seemed unaccountable when we could not understand a word she tried to say when endeavoring to talk to her friends. This condition might perhaps be accounted for on the ground that she knew the alphabet and numbers by heart, but was unable to originate language in the way of conversation.

The extravasation of blood in the brain must, in her case, have compressed the origin of the nerves, the function of which enables us to command language.

About ten days before her second attack she began to lose the use of herself, and could not walk without some assistance, although her appetite remained as good as usual, still eating at the table.

On the night of February 10, just five months after the first attack, she had the second. I was sitting by the bedside when it came on. I noticed several minutes before that the blood vessels about the head and face were congested; and as she seemed to be losing consciousness, I felt certain another attack was approaching. In a very short time she had a slight spasm, a mere sudden jerk; and she was perfectly motionless and unconscious. She never regained consciousness or any muscular action, and lived only thirty hours.

I spoke, in the outset, of some peculiar symptoms attending this case. I have mentioned one, her inability to command language to express herself in trying to talk with her friends, and the ability to repeat words she had been familiar with all her life, such as counting numbers and repeating the letters of the alphabet.

Another unusual symptom was the change in her habits for about a month before she was stricken down. She was always a great reader and talker, but for several weeks before she was taken ill she had but little to say in the way of conversation and she read but little. Before this, she always read some in the Bible every day and was fond of reading religious papers, but now she would only read a paper a few minutes and lay it down. This change in her habits was remarked by her friends, but, of course, could not be accounted for. From the history of the case I feel satisfied that there was some change then taking place in the brain substance.

The results of apoplexy vary according to the amount of blood extravasated into the brain substance and amount of pressure resulting therefrom.

Hemorrhage in the cerebellum is much more apt to prove fatal suddenly than in other portions of the brain. In fact, many cases fall and die immediately. Those who escape sudden death are afflicted with hemiplegia on the side opposite to that of the hemorrhage, the nerves decussating to the side opposite their origin. Probably half of the cases recover so they can walk, and have good use of themselves, except the hand of the hemiplegic side. Some who recover their health in every other particular never regain the proper use of the hand, but now and then a patient recovers the use of all parts of the paralyzed side. I have had two cases attended with this result. Of course this depends entirely on the amount of blood extravasated into the brain and on the severity of the attack.

The exciting causes of apoplexy are somewhat indeterminate. A person may be in an excellent state of health and be stricken very suddenly. This may occur without any premonitory symptoms or indications. It may occur while sitting, standing or walking, without mental excitement or physical effort.

But, no doubt, in some instances there exists some diseased condition of the brain, or pathologic alteration in its structure favoring hemorrhage.

Then again, the attack may occur during great mental excitement or physical exertion. Whatever may increase the circulation or retard the blood from returning from the brain may result in an attack. The treatment of such cases, of course, is simple but essential. The patient should be kept as quiet and comfortable as possible, with the head and shoulders somewhat elevated by pillows. The room should be well ventilated and kept perfectly quiet; in fact, anything calculated to produce excitement must be excluded from the patient. His diet should be light, but digestible and nourishing.

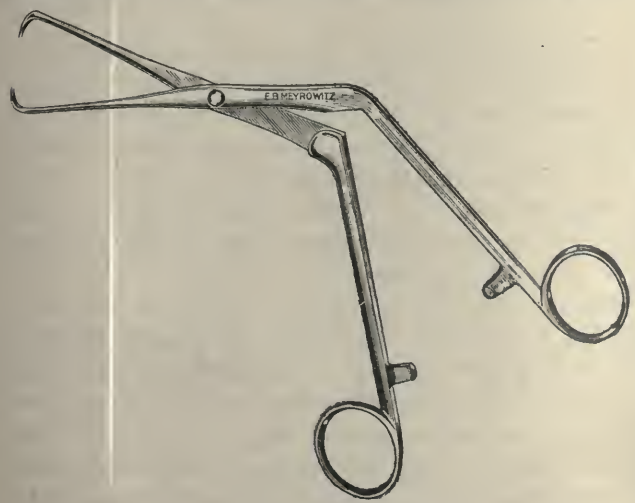
In old times venesection was practiced in such cases, and at present, if the patient is robust and stricken down in perfect health, there is no doubt that the abstraction

of blood by venesection would prove beneficial. But, by doing so, we would have to revive a lost art in surgery.

It is very essential that the bowels should be kept well relaxed, so as to determine, as much as possible, from the head in the way of revulsions. The kidneys should also be kept active, in order to modify the quantity of blood in the veins.

The action of the heart should be looked after and kept in moderation. If there is apparent congestion about the head, it would be well to apply cloths wrung out of cold water and hot applications to the lower extremities, etc.

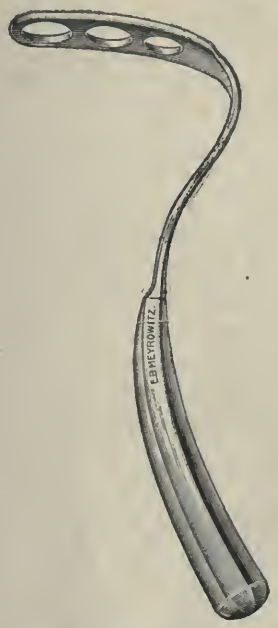
Apoplexy is much more common now than formerly. During the census year of the United States, 1900, there were 50,766 deaths from the disease; 27,059 males and 23,707 females; the proportion of deaths from apoplexy and paralysis in 1,000 deaths from all causes was 50.8; whereas, in 1890, ten years before, the corresponding proportion was 37.6 per 1,000 from all causes. In fact, there are other diseases, aside from apoplexy, which are more common now than years ago and, apparently, more fatal. We might name, and very conspicuously so, pneumonia. During the winter and spring seasons we frequently notice in the weekly reports of mortality in cities that more people die from the effects of pneumonia than from the much-dreaded white plague, tuberculosis.



Fortunately, the latter disease is not so prevalent and fatal as formerly, this change taking place within the last decade. It has decreased from 12,146 deaths in 1890 to 10,688 in 1900 per 100,000 deaths from all causes. This happy result has been brought about by the use of preventive means and a better mode of treatment.

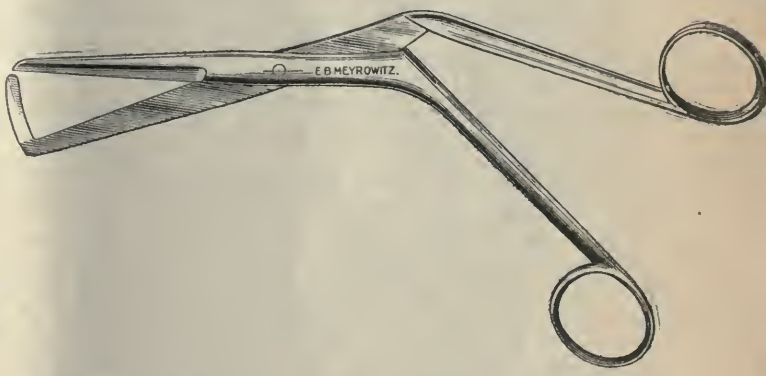
New Instruments.

A NEW TONSIL SCISSORS, FORCEPS AND TONGUE DEPRESSOR.



C. C. STEPHENSON,
LITTLE ROCK, ARK.

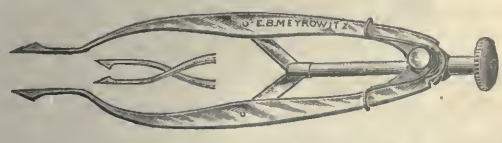
The operation for tonsillotomy with these instruments, and the advantages they possess, are briefly as follows: The forceps are made to seize the tonsil, when the handles are locked with



fixation ratchet; the tonsil is then drawn out, the beak of scissors is passed behind, and the gland cut off entirely, as in cutting with an ordinary scissors. The beak prevents the tonsil from slipping from between the blades of scissors, and so much of the tonsil can be removed as is desired. While holding it with the forceps the tonsil is completely under control of the operator; thus there is no receding of the gland as in the ring of a tonsillotome.

The simplicity and ease in operating commend the scissors and forceps, while with them the removal of entire gland without trouble is a desideratum. The handle of the tongue de-

pressor is octagon, and curves outward, thus allowing an examination of the full-chested class of patients, without the end of



the handle coming in contact with the chest. The blade has three holes for the dorsum of tongue to project through, which prevents it from slipping from side to side while in use.

IMPROVED TENDON TUCKER.*

FRANK C. TODD, M.D.
MINNEAPOLIS.

I desire to show the Section a tendon tucker, which is an improvement over my instrument shown at the session last year. The principle of this instrument is the same, the only

difference being that the adjustment is made at the distal end of the instrument, where it is more easily handled. The operation was described in the *Ophthalmic Record*, February, 1902.

THE MILK SUPPLY OF CITIES AND TOWNS.

Milk is so important and so valuable an article of diet, particularly for children and invalids, that every measure calculated to ensure its purity and improve its quality should be most heartily encouraged. Contamination and deterioration may take place so readily that only the utmost vigilance at all steps between production and consumption will secure freedom therefrom. To act intelligently in the matter requires a knowledge of the sources of danger, as well as of the means for combating them.

The subject of the milk supply has received considerable attention of late, particularly with reference to the feeding of infants, and in several large cities—Philadelphia, New York, Chicago, etc.—commissions composed of medical men have been organized for the purpose of devising ways and means for the attainment of the desired end, and with most promising results. Essex county, N. J., has for ten years had a medical milk commission, which gives its endorsement to the milk of such dairymen as will enter into an agreement as to the care of their cows, the collection, handling, preparation for shipment and transportation and delivery of their milk. Nor has the subject been neglected by the producers of milk, who are now giving increased care to the selection and breeding of their cows, as well as to the housing and feeding of the stock, and to the details of the milking, packing and transportation; while the milkman, in his turn, has striven to supplement the efforts of the dairyman.

For the purpose of determining what has already been accomplished in the improvement of the milk supply, together with the measures that have been found efficacious, and with the object of guiding new movements or reviving old ones in the same direction, the Bureau of Animal Industry of the United States Department of Agriculture has, through the chief of its dairy division, Mr. Henry E. Alvord, and his assistant, Mr. R. A. Pearson, made a study of the milk supply of 200 cities and towns. The report, from which we have already quoted in our news columns, is based on official documents and special reports from officers charged with the enforcement of so-called milk laws and ordinances. It deals with the legal requirements as to market milk in every state and territory having laws on the subject, and includes a more or less detailed account of the milk supply of all of the 161 large cities in the United States having a population of more than 25,000 each, and also of thirty-nine selected cities and towns of smaller size.

As an evidence of the magnitude of the industry it is estimated that 1,000,000,000 gallons of milk are sold annually by the owners of producing cows for consumption in the natural state or for household purposes. It is further pointed out that so much has been said and written regarding impure market milk that many persons have become unnecessarily alarmed, and for this reason any fair inquiry into the subject that will elicit the facts in the case and suggest steps to be taken for the benefit of the industry should be welcomed by milk inspectors and consumers, as well as by milk producers and dealers. It was found that the average quantity of milk per capita provided in the daily supply, and presumably consumed, in the large cities (that is, with a population above 100,000) is 0.61 pint. In cities with a population between 50,000 and 100,000 the average consumption is 0.63 pint; in cities with a population between 25,000 and 50,000, 0.58 pint, and in cities and towns with a population of less than 25,000, 0.57 pint. For individual cities the amount varies between 0.27 and one pint. Skim milk is used by some cities in addition to whole milk up to about one-third pint daily per capita, while in other cities no skim milk at all is used. The quantity of cream used daily in the larger cities varies from 0.01 to 0.19 pint per capita. Producers usually receive on their farms from 2 to 3 cents per quart in the summer and 3 cents or more in the winter, although lower and higher prices respectively are exceptionally received. The average price paid by consumers of milk, when retailed in small amounts, is about 6 cents in summer and 7 cents in winter. The cost may be slightly enhanced by the exercise of close supervision of milch cows and the adoption of precautions necessary to insure milk of high quality and purity from both the chemical and bacteriologic standpoints, but the public has not yet learned to appreciate the advantages of such protection.

The delivery of milk and cream in glass jars is increasing in favor and has distinct advantages. The jar constitutes an accurate measure; it can be readily sterilized and its contents are protected from contamination. Pasteurization of market milk is not generally practiced, only a few cities reporting a small portion as being thus treated, although the practice appears to be gradually extending.

Laws referring to market milk are on the statute books in thirty-five states, while nine other states and territories have enacted pure-food laws having a bearing on the milk supply, but only twenty-six states have officials whose especial duty it is to enforce these laws. Almost every city and many towns and villages have ordinances or board of health regulations concerning the milk supply. With few exceptions, there is some supervision of the milk supply in all cities of the United States having a population over 50,000. Much less supervision is exercised in cities with a population

between 50,000 and 25,000, and in small cities and towns supervision is the exception rather than the rule. This consists principally in testing samples of milk to ascertain if they contain the proper amount of cream and solids, while inquiry into the health of the cows furnishing the milk and of the persons handling it, and into the conditions to which it is subsequently exposed, is too often ignored.

Among improvements that have recently been instituted and suggested are the following: The registration of all dairies; official endorsement of properly conducted dairies; inspection of all herds, barns, dairy buildings, etc., once a month; better lighting, ventilation, drainage and cleanliness of cow stables; whitewashing the interior of stables; eradication of tuberculosis from dairy herds; branding of condemned cows; cows not to be given swill feed, etc.; cows to be regularly cleaned; pasturage for city cows; aëration of milk in pure air; prompt cooling of milk and holding it at low temperature until final delivery; shipment of milk promptly from farms after milking; delivery of milk and cream in sealed packages (glass bottles or small cans), so as to avoid unnecessary contamination by city dust, etc.; delivery of milk in cities at any hour of the day when it can be supplied in the best condition; restrictions on the sale of milk in markets, candy stores, etc.; delivery of milk from such stores in bottles only; mixing of herd milk so as to get an article of uniform composition; bottling of milk only at the dairy or place of general supply; daily sterilization of milk utensils; more rigid inspections for preservatives in milk; chemical and bacteriologic examinations of milk; standards for cream and skim milk; the passage of no law that can not be reasonably well enforced; more pay and allowances and greater authority for milk and dairy inspectors; more severe penalties for violation of milk laws; publication of reports on inspection of dairies; education of milk producers by a liberal distribution of circulars, leaflets, etc., bearing on their work.

DISEASE AND MUNICIPAL RESPONSIBILITY.

Human life has become more precious in recent years, and human suffering has taken on the significance of an evil that must, as far as possible, be avoided at any cost. Accidents and death have lost most of their calm acceptance as inevitable results of providential conditions, and strict accountability is demanded. It would be well if the same thing were more true with regard to disease than has been the case up to the present time. Modern medical progress has taught very definitely what are the exact causes of many diseases, and we know now that in most cases when infectious disease affects a particular individual it is not usually (though, of course, it may be) because the person has "caught" the disease, as used to be said, but it is because some one has blundered and thus made it possible for the disease to be communicated in an unsuspected way.

Typhoid fever we now know to be due to the ingestion of the typhoid bacillus. The typhoid bacillus comes from the excretions of a patient suffering from the disease. Unless the assumption that forms the basis of the science of bacteriology is wrong, the disease germ never arises by any chance *de novo,* never originates spontaneously. If typhoid stools and urine were cared for as they should be, and as modern medical practice has made it rather easy for them to be, there should be no further cases of typhoid fever. An enthusiastic sanitarian said not long since, with regard to this question of cause and effect in typhoid fever, that when a person dies of typhoid fever some one should be hung. There is no doubt that a criminal responsibility attaches to the neglect of precautions which would make impossible the communication of typhoid fever to those as yet unaffected by it.

These considerations are of special interest at the present time when we are entering on the season of the year in which typhoid fever is more frequent than at any other and when the death rate from the disease always becomes an important factor in the mortality of most of our large cities. Some of the reasons for this prevalence of typhoid at this season are well understood. The main factors in its distribution are water and such food materials as milk, oysters and certain vegetables that are eaten raw. These articles of food and drink are not dangerous unless there has been some serious neglect with regard to the precautions necessary to protect them from infection by typhoid bacilli. Of all of them by far the most important is the water supply, and this is usually under the care of the municipal authorities, or if supplied by private parties it is under a franchise from the municipal government.

It is only logical to conclude that under these circumstances legal criminal responsibility should hold against the municipal authorities or against those to whom they have granted a franchise if it can be shown that there has been neglect of proper precautions in the matter. A half century ago large corporations were able to shirk their responsibilities for accidents, much more readily than at the present time, but, fortunately, a proper sense of their obligations in such matters has grown up in our communities, and it is well understood that damage suits will follow bodily injury.

It seems not improbable that a corresponding state of affairs will have to come to pass with regard to responsibility for disease. There is no doubt that large corporations are much more careful in guarding against accidents and injuries, since it has become a matter of costly experience that their responsibility for them will always be held strictly to account. Perhaps municipalities will come to something of the same realization under the stress of similar conditions.

Certainly at the present moment nothing is more discouraging in social affairs than the fact that citizens somehow do not consider municipal responsibility as ac-

countable for the suffering, often permanent injury and frequently death that is inflicted by municipal neglect in these important matters.

There is room for improvement in the civic sense of our American communities. Citizens must come to the realization of what is owed to them by city governments in the matter of protection for health, and now as the precautions necessary to secure proper sanitation in every way are so well understood, failure should be followed by immediate legal reclamation. It would seem that physicians owe it to their fellow citizens to make them understand that responsibility for disease is quite as direct as that for accidents. We can foresee that the awakening of such a feeling will be followed by further progress in the healthfulness of city life.

INFANT MORTALITY AND THE LAW OF NATURAL SELECTION.

Those persons who are wont to strengthen a comfortable optimism by extracting sunshine from cucumbers have often urged the view that the high infant mortality that is so characteristic of city life in our time is, from the racial standpoint, not altogether deplorable. The specious argument runs that through the stress of environmental conditions the weaker individuals in each generation are eliminated during the period of infancy, and that, therefore, the adult population in those districts where infant mortality is high must be more vigorous than if the weaklings were able to develop to maturity. It has been asserted that in places having a high infant mortality, the mortality in the succeeding years of childhood is actually lower, the average fitness of the male population for military service greater and tuberculosis less prevalent. Statistical evidence has been adduced in support of this view, especially by Oesterlen, who has maintained with a show of figures that those districts in Europe having a large death rate among infants exhibit a lower mortality during the succeeding years of childhood than do those countries in which the infant mortality is small. The implication is that a high death rate during the first months of infancy must in the long run benefit the race by weeding out the weaker and less fitted to survive. In some quarters fear has been expressed lest too great devotion to the task of preserving feeble infants may lead to a deterioration in the physique of future generations.

From one point of view the preservation of weakly infants needs no defense. The world has been too often the debtor to men of feeble constitution to be willing to admit that only those of strong physique are of value in advancing the knowledge and well-being of the human race. The present generation, with its eyes fixed on the importance of definite material accomplishment, may perhaps need the reminder of Mr. Bliss Perry in his recent brilliant essay on indifferentism that "None of our contemporary hallucinations leads more certainly to ultimate weariness and indifferentism than this too exclusive glorification of 'men who do things.' . . . If we have purchased speed and power at the cost of nobler qualities, if the men who do things are bred at the expense of the men who think and feel, surely the present American model needs modification." But although the idealist and what he stands for may not be conspicuous in the columns of the American daily newspaper, there are many reasons for believing that the kind of success due to great energy and dominant physical power is not the only thing that at present looms large in the minds of many Americans. Huxley has expressed himself on this matter of selecting good citizens with a characteristic touch of scorn for the "saviors of society": "I doubt whether even the keenest judge of character, if he had before him a hundred boys and girls under fourteen, could pick out with the least chance of success those who should be kept, as certain to be serviceable members of the polity, and those who should be chloroformed, as equally sure to be stupid, idle or vicious. The 'points' of a good or of a bad citizen are really far harder to discern than those of a puppy or a shorthorn calf." The assumption that physical vigor in infancy constitutes any criterion of the future significance of the individual to the race may be dismissed as a crudity of a one-sided conception of human life.

From the standpoint of bodily energy or simple physical vigor, the natural selection argument may still retain an element of plausibility. Prinzing, however, in a recent searching criticism[1] of the doctrine advanced by Oesterlen and others, reinforced by extensive statistical material, is utterly unable to find any reason for believing in the existence of correlation between high infant mortality and either a diminished mortality in the early years of childhood, superior physical qualifications for military service, or a low death rate from tuberculosis. In none of these respects do communities that are favored with a high infant mortality possess any advantage over those in which the infant mortality is low.

It is not surprising that this should be the outcome of Prinzing's statistical inquiry when we reflect that by far the larger number of deaths among infants in the first months of life are due not so much to congenital weakness as to errors or misfortunes of nutrition. The quality of the food to which a young infant has access is the great leveler, and does far more than robustness at birth to determine whether the young Darwin or Pasteur or Roosevelt shall perish or survive. Little alarm need be felt, therefore, at the efforts now making to lower the excessive infant mortality in the chief centers of population. It is safe to assume that these endeavors are not running counter to the law of natural selection, and will not necessarily result in a survival of either the physically or the intellectually unfit.

ASEXUALIZATION OF CRIMINALS.

A Baltimore grand jury has recommended the asexualization of those convicted of criminal assaults on

1. Centralbl. f. allgem. Gesundheitspfl., 1903, xxii, p. 211.

women, and especially on young girls, thus giving a sort of judicial or official recognition to the proposition that has been repeatedly made by private individuals. That it will be acted on at the present time is rather more than doubtful, but it shows a tendency that may grow even to the point of actual legislation at some future time. Such a punishment might be construed as unconstitutional, but it would at any rate be better than lynching, which is getting so common in some sections that its peculiar methods can almost escape the constitutional provision against "unusual" punishments. Whether the proposed method would be considered unconstitutional we are not prepared to say, but it would be comparatively humane and for a certain class of criminals more effective than the usual methods.

THE LUST OF SLANDER.

Referring to our editorial last week under the above caption, we are glad to report that Dr. Leffingwell has made a "reply" in the last issue of *American Medicine*. The reply is evasive. Dr. Leffingwell does not deny or disprove that his remarks have created an impression warranting the reference to them in the British antivivisection journal. We must judge utterances by the impression that they are evidently intended to convey rather than by their literal verbal text which may favor quibbles and an evasive answer. It seems clear to us from Dr. Leffingwell's own showing that he had brought out the charge that vivisection was carried on for infamous purposes, and no man recognizing its value and not wishing to convey false impressions would have allowed himself to speak so as to permit of such inferences. We do not think he has cleared up the case as far as his own responsibility is concerned, though he has said enough to spoil his testimony for the antivivisectionists.

Medical News.

CALIFORNIA.

Fullerton Hospital Completed.—The new hospital at Fullerton has been turned over to the board of directors by the contractors. On August 13 the building was formally opened. It has 21 rooms in all and is thoroughly equipped.

Vital Statistics.—In San Francisco during July 500 births were registered, a rate of 14.62 per 1,000 per annum; during the same period 609 deaths were recorded, equivalent to an annual death-rate of 17.82 per 1,000. Violence caused 50 deaths.

Two More Cases of Plague.—The ninety-eighth case of bubonic plague in San Francisco was that of Lee Jim, a Chinaman, who was found dead July 20. The diagnosis was confirmed by autopsy and by bacteriologic tests.——On August 9 W. Bock, a German, of Pacheco, Contra Costa County, died at a San Francisco hospital, and the autopsy established the diagnosis of plague. This is the ninety-ninth case.

Aids State Medical School.—Regarding the relation of the State University to its affiliated medical department, which was discussed at the recent meeting of the board of regents of the university, the superintendent of public instruction states:

> After considerable discussion it was agreed to supply temporary relief to the school, by authorizing its financial committee to sell certain property that was willed to the institution by Dr. Toland, and to apply the money received to the financial aid of the school. The exact status of this department will be an important question for future decision. the regents being about equally divided in opinion as to whether to assume full control of the school or to cut away from it entirely and allow it to shift for itself.

New Laboratory at State University.—The dedication of the Loeb Physiological Laboratory of the University of California took place on August 20. The dedicatory address was delivered by Prof. Wilhelm Ostwald of Leipsic, it being delivered in German, but a full translation was published in the San Francisco papers, as was also the address of Dr. Loeb. The Loeb Laboratory is the gift of Rudolph Spreckels, who furnished $25,000 for the purpose, beside a large part of the equipment. Dr. Herzstein also assisted in equipping the laboratory. Mrs. W. H. Crocker gave a library. An anonymous friend of the university furnished the means of paying Dr. Loeb's salary.

Personal.—Dr. Benjamin A. Plant, physician at the State Penitentiary, Folsom, has resigned.——Dr. James P. Dunn, Oakland, has been appointed chief surgeon of the Southern Pacific Railway in Alameda County.——Dr. Charles E. Turner, Vallejo, has been elected secretary of the local board of health, vice Dr. Walter D. Anderson, deceased.——Dr. Bertram F. Alden has been elected chief surgeon of the French Hospital, San Francisco, succeeding Dr. F. P. Canac-Marquis, resigned.——Dr. J. Denis Arnold, San Francisco, was recently thrown from his horse at Council, Alaska, spraining and wrenching his ankle seriously.——Drs. Edward Henderson, Isaac N. Hughey and Thomas J. Wilson have been appointed members of the Pomona Board of Health.

COLORADO.

July Deaths.—During July 774 deaths occurred in the state, equivalent to an annual death-rate of 15.67 per 1,000. Of these, 12 each were caused by diphtheria and typhoid fever, 3 by smallpox and 2 by scarlet fever.

College Opens.—Denver and Gross Medical College, Denver, opened for its second year September 14, with addresses by Chancellor Henry A. Buchtel, Dr. Edmund C. Rivers, president, and Dr. Leonard Freeman, vice-dean, of the institution.

Personal.—Dr. Arnold Stedman, Denver, was operated on for appendicitis, September 3, and is reported as doing well.——Dr. Elsie Reed Mitchell, Denver, leaves for India, October 1. She will take charge of the Lutheran Hospital at Guntur.

Communicable Diseases.—During July 126 cases of diphtheria, 64 of scarlet fever, 133 of smallpox, and 55 of typhoid fever were reported to the State Board of Health. Compared with the previous month, this shows a decrease of 40 cases of diphtheria, 41 of scarlet fever, and 54 of smallpox, and an increase of 30 cases of typhoid fever.

CONNECTICUT.

New Britain Hospital.—The new hospital building, erected at a cost of more than $20,000, is expected to be ready to receive patients some time this month.

Hospitals Incorporated.—The New Haven Emergency Hospital and the Eastern Emergency Hospital of New Haven, with capital stocks of $5,000 and $2,500 respectively, have been incorporated.

Medico-Military Changes.—Major Rockwell, surgeon First Infantry, C. N. G., has been placed on the retired list; Assistant Surgeon John B. McCook, Hartford, has been appointed surgeon-major, and Dr. Herman A. Tyler, Jr., Hartford, surgeon-lieutenant, both being assigned to the same regiment.

Wickerwork Coffins.—Dr. Charles A. Lindsley, New Haven, secretary of the State Board of Health, advocates burying the dead in wickerwork caskets instead of the usual wooden or metal coffins. The body of the deceased, he said, might sooner come in contact with the earth and be more quickly destroyed. This would be a more sanitary method than the present one.

GEORGIA.

Unqualified Practitioner Sued.—Frances McCandless of Atlanta, a graduate of the American Health College of Cincinnati, an institution incorporated with the object of "teaching and practicing the Religious Spiritual Vitapathic System of Health and Life for Body and Soul," has, nevertheless, been sued by an ungrateful patient for $20,000 damages, for alleged malpractice.

The Grady Hospital Matter.—The committee on hospitals and charters appointed to investigate the rules of the Grady Hospital, Atlanta, in its report endorses the present management of the hospital; and recommends that the entire board of trustees act in the management instead of an executive committee; that the pay department of the hospital be abolished after Jan. 1, 1904; that the number of trustees be reduced to 7; that the out-patient department be abolished; that visiting hours be allowed on Sunday, and that information regarding the affairs of the hospital be freely furnished to the public.

The State Board of Health.—At its first meeting, September 10, in Atlanta, the board was organized, a constitution and by-laws adopted, and Dr. Augustus P. Taylor, Thomasville, elected president *pro tem.*, and Dr. Robert M. Harbin, Rome, secretary *pro tem.* After the organization the following officers were elected: Dr. Willis F. Westmoreland, Atlanta, president; Dr. H. F. Harris, Atlanta, secretary for six years; Drs. Charles Hickes, Dublin, Samuel C. Benedict, Athens, James B. Morgan, Augusta, and Howard J. Williams, Macon, committee on general powers and duties; Drs. H. F. Harris, Atlanta, William W. Stewart, Columbus, and Robert M. Harbin, Rome, committee on diseases common to man and animals, and Drs. Augustus P. Taylor, Thomasville, Giles Hathcock, Belton, and Millard S. Brown, Fort Valley, committee on sanitation and vital statistics.——Dr. F. M. Ridley, La Grange, having declined appointment on account of ill health, the governor has appointed Dr. William W. Stewart, Columbus, a member of the board.

ILLINOIS.

Offender Provisionally Released.—On her promise to refrain from practicing medicine, Mrs. Edith Nail, Pekin, who was arrested a short time ago on the charge of illegal practice, was released September 10.

Physician's Register.—The 1903 "Report on Medical Education" of the Illinois State Board of Health will be issued in about two weeks. This report includes an official register of physicians, corrected to Sept. 14, 1903. Illinois physicians desiring a copy of the report should write to the secretary of the State Board of Health, Springfield.

Skeletons Found in Sanatorium.—In a building formerly occupied by Dr. Carl L. E. Weber, Quincy, as a private hospital for women, in which three skeletons were found a year ago, two more skeletons were found, September 4. While it is supposed that these skeletons are of patients who died in the hospital, Dr. Weber will not be prosecuted as, it is alleged, he is at present under restraint, a mental and physical wreck.

Does Running Water Purify Itself?—Sanitary experts, physicians and bacteriologists representing the Chicago Drainage Board left Chicago, September 16, for a trip down the drainage canal and the Illinois River to St. Louis for the purpose of examining the water along the route and ascertaining whether germs are carried from Chicago to St. Louis. The Sanitary Trustees declare that the river purifies itself long before reaching St. Louis.

Examination for Medical Officers.—In conformity with the new military code adopted by the last general assembly requiring that all medical officers of the National Guard shall be examined as to their competency, the following are ordered to report to General Nicholas Senn in Chicago, September 26, for examination: Charles J. Sowle, first lieutenant and dental surgeon, assigned to Third Infantry; Walter J. Brown, Danville, first lieutenant and assistant surgeon, assigned to artillery battalion; Horace H. Sheets, first lieutenant and assistant surgeon, assigned to Third Infantry; Arthur F. Wilhemy, Decatur, first lieutenant and assistant surgeon, Fifth Infantry; William H. Maley, Galesburg, first lieutenant and assistant surgeon, artillery battalion, and Levi S. Brown, first lieutenant and veterinary surgeon, assigned to artillery battalion.

Chicago.

Hospital Buys Land.—George B. Swift has sold to the Frances E. Willard Temperance Hospital property 24 by 115 feet on Lincoln street, for $1,000.

Personal.—Dr. Frank E. La Force has returned after a month on the Pacific Coast.——Dr. and Mrs. G. E. Fosberg have returned from abroad.——Dr. Denslow Lewis has returned from a year's residence in Berlin.

No Ground for Alarm.—The health department says diphtheria is not so prevalent as usual in the city at this season of the year. There were only 10 deaths from the disease reported during the week, as compared with 14 during the week before. There will undoubtedly be an increase as cold weather approaches from the effects of huddling together in badly-ventilated rooms, both at home and in school.

Deaths of the Week.—Deaths from all causes for the week ended September 12 numbered 504, or 40 more than for the previous week, and 10 more than for the corresponding week of 1902. Acute intestinal diseases head the list of death-causes with 92; then come in order, consumption, 57; violence, 41; heart diseases, 39; Bright's disease, 34; nervous diseases and pneumonia, each 22, and typhoid fever, 21. The deaths represent an annual death rate of 13.94 per 1,000.

Meddlesome, Mischievous and Sensational.—In these terms the department of health characterizes the recent attempt to the superintendent of compulsory education to operate a special health department:

> Physicians of Chicago, school principals and teachers and parents of school children are officially notified that they are not required, either by state law or city ordinance, to report cases of contagious disease, suspected or actual, to any authority except the Contagious Diseases Division of the City Health Department.
>
> This public notice is made necessary by a renewal of the efforts of the superintendent of compulsory education of the school board to operate an independent health department of his own. His motive is no doubt a laudable one, and if his efforts were guided by a moderate degree of professional intelligence and qualification for the work they might be beneficial instead of detrimental. As it is they are meddlesome, mischievous and sensational.

INDIANA.

Typhoid Raging at Norwood.—It is reported that typhoid fever is raging at Norwood, a suburb of Indianapolis, where 21 cases of the disease existed on September 10, with very bad sanitary conditions.

To Restrain Eddyism.—The State Board of Medical Registration commenced the prosecution of Eddyites, August 21, when affidavits were placed in the hands of the states attorney, charging Anna B. Dorland and Laura Funk, Indianapolis, with practicing medicine without license.

New Hospital for Michigan City.—Contracts for the construction of St. Anthony's Hospital, Michigan City, have been awarded by the Order of Franciscan Sisters. The building is expected to cost about $60,000, and is to be ready for occupancy next spring. The cornerstone is to be laid October 11.

Personal.—Dr. William C. Willeford, Washington, had a narrow escape from death by atropin poisoning recently. ——Dr. Theodore C. Sargent has been appointed surgeon at the State Soldiers' Home, Lafayette, vice Dr. John A. Martin, resigned.——Dr. Barnhardt Erdman, Indianapolis, has sailed for Europe.

Smallpox.—There were 112 cases of smallpox reported in August from 29 counties, with 12 deaths. In the corresponding month last year there were reported 245 cases in 30 counties, with 2 deaths. The decrease in cases, it will be noted, was 130. The area was decreased by one point and the number of deaths increased 500 per cent. These figures indicate an increased virulence.

August Deaths.—The total number of deaths reported was 2,933, an annual rate of 13.7 per 1,000. In the corresponding month last year there were 3,158 deaths, a rate of 14.8 per 1,000. Deaths under 1 year were 598, or 21.3 per cent. of the total. Deaths 65 years and over, 630, or 22.8 of the total. The consumption deaths numbered 259, typhoid fever 108, diphtheria 21, scarlet fever 8, measles 3, whooping cough 10, pneumonia 79, diarrheal diseases 451, cerebrospinal meningitis 37, influenza 10, puerperal fever 10, cancer 124, violence 165, and smallpox 12. The country death rate was 11.8, the city death rate 17.4 per 1,000. The country rate was less in all but three diseases, namely, scarlet fever, measles and influenza.

Morbidity for August.—The public health was not quite as good as in the preceding month, but was better than in the corresponding month of last year. Typhoid fever increased greatly over the preceding month, the deaths being respectively 108 and 63. There were fewer typhoid deaths, however, than in August, 1902. The order of prevalence of disease was as follows: Typhoid fever, diarrhea, cholera infantum, cholera morbus, rheumatism, dysentery, intermittent fever, tonsillitis, bronchitis, inflammation of bowels, scarlet fever, diphtheria, influenza, pneumonia, erysipelas, measles, whooping cough, pleuritis, cerebrospinal meningitis and puerperal fever.

Resolutions Regarding Contract Work.—At the meeting of the Henry County Medical Society held at Spiceland, June 25, the following resolutions were adopted:

> WHEREAS, One of the principal objects of our organization is to enable its members to receive just and full compensation for their services;
>
> WHEREAS, The rapid building of traction lines, whose construction and operation are fruitful causes of accidents and injuries, is of vital importance and interest to the physician and surgeon;
>
> WHEREAS, Traction companies are offering to make contracts with physicians and surgeons, wherein the sole compensation for the services of the latter consists of passes over the lines of said companies; (See copy of contract appended.)
>
> WHEREAS, This appeal to the vanity, jealousy and envy of the surgeon tends to debase the dignity of the profession and therefore calls for imperative action on the part of this society; therefore, be it
>
> *Resolved*, That it is the sense of this society that entering into contracts with traction or other companies, to serve them without just and full compensation is undignified, unprofessional and in-

jurious to the profession, and that we should not enter into such contracts and to do all in our power to discourage others from entering into them;

Resolved, That a copy of these resolutions be sent to each physician in Henry County, requesting his co-operation in carrying out the same.

SAMPLE CONTRACT.

..... TRACTION COMPANY OF INDIANA.

I, ..., M.D., of ....., Indiana, hereby propose and agree to serve the ..... Traction Company of Indiana as surgeon at ....., Indiana and vicinity, for the consideration of an annual pass for myself, over the Interurban Lines of this Company, and in the event of the acceptance of this proposition I hereby agree:

1st. To attend professionally to the best of my ability all cases of personal injuries received by employés of said Company or by any other persons, whether passengers, highway travelers or others, arising directly or indirectly from or in the management, operation or business relating to said Company or where such injuries occur upon the property of said Company, and to furnish the necessary dressings and medicines while attending these cases; and to promptly report each case on the proper blank furnished for this purpose.

2nd. To go to any point upon the Company's lines and give the necessary attention to the injured persons, when requested in cases of emergency, also to attend any case of injury as above named when brought into my vicinity.

3rd. To examine persons who claim to have been injured in a manner aforesaid when requested, and make a prompt report to the Company, and attend court to give testimony in regard to such cases without extra compensation, also to vaccinate employés and make physical examinations of them when requested.

4th. To provide, at my charge and expense, the necessary attention above specified, by a competent surgeon in my absence or disability.

KANSAS.

Illicit Sale of Cocain.—P. P. Aherne, a druggist of Wichita, has been arrested on the charge of selling cocain and morphin without the prescription of a physician.

New Asylum to Open.—The new state hospital at Parsons, intended for the use of epileptics only, will be opened some time this month. The buildings thus far erected will accommodate 165 patients, but the intention is eventually to enlarge the buildings to a capacity of 1,000.

Too Much Calomel.—Dr. Olin P. Wood, Hall's Summit, has been sued by J. P. Stukey, who alleges that the defendant gave him mercury and calomel in excessive amounts and with undue frequency, whereby he was salivated, etc. He asks $1,000 damages.

Asylum Abuses.—The committee appointed by the governor to investigate alleged abuses in the state hospitals for the insane, embodies in its report the following:

The committee finds that there exists in the wards, among the attendants, careless practices in the handling of patients that frequently amount to unwarranted force and punishment, and sometimes to cruelty.

There exists among the attendants a kind of secret understanding which has the influence of restraining one attendant from informing the superintendent or other superior of cases of misconduct and abuses on the part of other attendants toward the patients.

KENTUCKY.

Smallpox.—Dr. Uriah L. Taylor, Columbia, reports 19 cases of smallpox in the eastern part of Adair County.——At Washington, Daviess County, 16 cases are reported.

Quarter System in Louisville Medical College.—The medical department of Kentucky University has decided to introduce the quarter system and continue in session the whole year.

Personal.—Dr. P. Richard Taylor, Louisville, dean of the Hospital College of Medicine, has just recovered from a serious attack of ptomain poisoning.——Dr. Hugh R. Manning, chief clerk to the pension agent in Louisville, has been asked to resign because of alleged infringement of civil service rules.

What Killed Caine.—Considerable interest has been aroused by the autopsy ordered by the insurance companies on the body of the late Paul Caine, who was drowned in the Ohio River several weeks ago. Drs. Samuel E. Woody, Philip F. Barbour, George W. Griffiths and H. L. Hunt are in charge of the investigation for the insurance companies; Drs. Henry M. Goodman, Henry A. Cottell and A. Harris Kelly for the Caine family. Strychnin was suspected to have been taken by the deceased prior to his going into the water for a swim, and it is on these suspicions that the examination has been ordered.

Vital Statistics of Louisville.—Health Officer Allen has just submitted his annual report for the fiscal year ended August 31. Among the diseases credited with the most deaths are the following: Tuberculosis, 449; heart disease, 329; pneumonia, 293; inanition, 184; diphtheria, 121; typhoid fever, 157; Bright's disease, 181; enterocolitis, 145, and meningitis, 101. Considerable space is devoted to the question of diphtheria, the death rate from which was 6.8 per cent. The disease was of a much more virulent type than in previous years. Prior to 1898 there were no records of contagious and infectious diseases. In 1898-9, with 189 cases, the mortality rate was 1.37; 1899-1900, 160 cases, with a death rate of 1.62; 1900-1, 317 cases, with a death rate of 16.22; 1901-2, 844 cases, with a death rate of 1.30; 1902-3, 834 cases, with a death rate of 6.08 per cent. Dr. Allen commends the city for its action in distributing free antitoxin to those children whose parents are unable to purchase it.

LOUISIANA.

Personal.—Dr. Felix Formento, surgeon of the Soldiers' Home, New Orleans, has resigned.

Milk Inspection.—The authority of the New Orleans Board of Health to inspect milk brought into the city by out-of-town dairies was established at a conference held between the state and city boards last week.

Proposed Pasteur Institute.—At the meeting of the board of administrators of the Charity Hospital, New Orleans, held September 7, the question of establishing a Pasteur addition to the hospital was discussed, but no definite action was taken.

Sanitary Report for August.—The sanitary officer of the New Orleans Board of Health reports: Diphtheria, 11 cases, with 2 deaths; scarlatina, 4 cases; variola, 1 case (colored), imported; typhoid fever, 79 cases in 66 premises, with 21 deaths, 13 white, 8 colored.

Sanitary Barber Shops.—At the last meeting of the New Orleans Board of Health a report was submitted recommending the sterilization of all implements used in New Orleans barber shops. The regulations are drawn up on the same lines as those adopted by New York and other cities.

August Mortality.—The August mortality showed an improvement on the record for the same month last year. White mortality 313, colored 173, total 486; giving a death rate for white of 16.54 per 1,000 per annum and for colored 25.01, or a total death rate of 18.81. The rate for August, 1902, was 19.98, 17.72 for white, and 27.82 for colored.

Lunacy Increasing.—It is said by Dr. George A. B. Hays that in Louisiana insanity is increasing at the rate of more than 10 per cent. a year, or five times as fast as the population. When he took charge of the Louisiana Insane Asylum at Jackson in 1896 there were 850 insane persons; there are now 1,550, an increase of 80 per cent. in seven years, while the population has grown only 15 per cent.

MARYLAND.

Baltimore Personals.—Dr. John G. Jay is at Wiesbaden, Germany.——Dr. Alexander D. McConachie has returned from abroad.——Dr. George W. Norris has gone to the White Mountains.

Families of Deceased Physicians.—The following have been appointed trustees of "The Fund for the Relief of Widows and Orphans of Deceased Members," founded by the Medical and Chirurgical Faculty at its meeting in April: Dr. Eugene F. Cordell, chairman, Drs. William Osler, Daniel W. Cathell, John W. Chambers and Robert W. Johnson. An effort will be made at once to start the project with $1,000.

Springs' Virtues Long Known.—In 1698 the provincial assembly empowered a body of trustees to purchase land for the erection of a hospital for the sick poor, at the "Coole Springs in St. Mary's County." This action was induced by the prevalence of an epidemic in the state. To this first Maryland hospital Gov. Francis Nicholson subscribed $125. The act authorized the purchase of 50 acres, including the said "healing fountains." Miraculous cures were reported from the use of these waters, which are still used for the supply of Charlotte Hall School, also a provincial foundation. It is of interest that the recognition of the powers of these springs formed part of the first Thanksgiving proclamation in Maryland.

Medical Points in Grand Jury Report.—The report of the grand jury contains some points of medical interest. The sanitary condition of the city is pronounced very unsatisfactory. Diphtheria, scarlet fever and typhoid fever during May, June and July were doubly as prevalent as last year. The improvements recommended are a modern sewerage system, improved pavements, abolition of slaughter houses in the city limits, a hospital for infectious diseases, improvement of the city's water supply, and the discontinuance of the practice of collecting refuse from hotels and lunch rooms by day. A lavatory at the entrance of the park is recommended. About three-fourths of the cases that come before the grand jury are of negroes, who in nearly all cases live together as man and

wife, without regard to the marriage law. It would be wise to compel these people to marry; if not, to punish them for adultery, thereby reducing the cause for a great deal of crime. Castration is suggested for the crime of assault on women, and especially on little girls, and the enactment of a law to that effect by the next legislature of Maryland, which meets this winter, is heartily recommended. Hanging no longer deters this class of depraved criminals. Such a bill was introduced in the last Pennsylvania legislature. The growing cocain habit is considered responsible for a great deal of crime.

MISSISSIPPI.

Publication of Results of Examinations.—The Mississippi State Board of Health, at its last meeting, May, 1903, adopted the following:

WHEREAS, The experience of this board shows a rapidly increasing number of applicants for license to practice medicine, who are decidedly deficient in the elementary branches of an English education and who are unable to comprehend the meaning of many plainly-written questions; whose early education is so meager that it is impossible for them to grasp the principles of medicine. Since this is an injustice to the public, and dangerous to the lives and health of the people of the State of Mississippi, be it

Resolved, That, in future, the names of the applicants who fail before this board, as well as the names of those who pass, shall be given out for publication, with the names of the medical colleges of which they are graduates. And, further, be it

Resolved, That the secretary of this board shall transmit to the various medical colleges whose graduates appear before this board a list of students from their colleges who fail, with the request that greater requirements in the elementary branches of an English education be made of students who matriculate at their schools.

NEW YORK.

On Road to Recovery.—Dr. George Blumer, formerly director of the Bender Laboratory, Albany, who was operated on for appendicitis September 1, is making a good recovery.

Pure Water for Lockport.—The fire and water committee of the common council was granted permission by the council to issue bonds for $2,000 and to use it for the employment of water experts and to sink test wells.

Barber Examiners.—The State Board of Barber Examiners has announced that it will begin prosecution immediately of the barbers of the state who have failed to secure licenses. A fine of $10 or 30 days in jail is provided.

Dinner for Dr. White.—Dr. William A. White, Binghamton, who has recently been made superintendent of the Government Hospital for the Insane, Washington, was given a farewell dinner by a large number of Binghamton friends, August 31. The employes of the hospital have presented Dr. White with a handsome Turkish rug.

New York City.

A Fasting Man.—A press builder of Brooklyn has undertaken a forty-day fast to demonstrate that it is possible for a man to live and work well on a diet of water. He began the present fast on August 22, at which time he weighed 173 pounds. On a former occasion, it is said, he went without eating for nearly three weeks.

Suspension, Protest, Reinstatement.—The suspension of one of the house physicians of Bellevue Hospital, Dr. W. B. Jones, has resulted in the drawing up of a formal protest by the house staff for presentation to the board of medical inspectors. The document complains of the uncivil manner in which the members of the house staff are treated by the superintendent of nurses, and asks that the authority of the superintendent be defined. Dr. Jones has been reinstated on condition that the authority of the superintendent is always to be recognized.

Research in Pathology and Bacteriology.—Cornell University Medical College has provided for a chair of experimental pathology and bacteriology to carry on research work, independently of the regular instruction given to undergraduates. Dr. Bertram H. Buxton is to be in charge, and will be assisted by Dr. Victor C. Vaughan, Jr. The pathologic organic chemistry, so intimately associated with all the problems of disordered metabolism, will be under the direction of Mr. Beebe. This work is to be entirely distinct from all undergraduate or postgraduate instruction and purely for the advancement of scientific knowledge, and is to be conducted in the Loomis Laboratory, a building originally designed especially for this purpose.

Health Department Projects.—It is the purpose of the health department to erect a one-story building next to the department's building, wherein medical aid will be rendered by the health department physicians to poor consumptives. A new hospital for the treatment of trachoma cases from the public schools is to be established in October, and hospitals for the same purpose are to be opened in the boroughs of Brooklyn and the Bronx. It is also planned to inaugurate an extensive system of sewerage and drainage near Coney Island and Sheepshead Bay and on Staten Island in the hope that mosquitoes and malaria may thus be exterminated. This last project will, of course, be expensive, but is to be paid for by assessments on the property benefited.

PENNSYLVANIA.

Philadelphia.

Increase in Typhoid.—Typhoid fever showed an increase for the week ended September 12, there being 135 new cases reported, as against 104 for the week before. The feeling prevails that smallpox is under control, there being only 7 new cases for the week.

Health Department and School Board Co-operate.—The department of health and the board of education are to co-operate in the inspection of the pupils of the public schools to determine in each case whether the child is properly protected by vaccination. When such protection does not exist parents are to be urged to have vaccination done either by the family physician or at the city's expense by a vaccine physician. Pennsylvania is much in need of a compulsory vaccination law.

Phipps Institute Chartered.—A charter has been granted to the Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis. The managers are now in a position to make plans for the permanent institution, involving an expenditure of $1,000,000, the gift of Henry Phipps. It has not been decided where the institute will be permanently located. The idea of the president seems to be that a thickly-populated section should be chosen, such as that now occupied by the temporary institute. The directors for the first year are Henry Phipps, Dr. Lawrence Flick of Philadelphia, president, and George E. Gordon of New York. An attempt will be made to have the International Congress of Tuberculosis meet at the institute in 1905.

SOUTH DAKOTA.

Adopt Resolutions.—The State Medical Society, at its recent meeting, adopted the resolutions concerning the examination of the eyes and ears of school children, which were recommended by the American Medical Association.

Personal.—Dr. James A. Somerville, for two years physician for the State Soldiers' Home, has resigned, and Dr. William S. Bentley, Gary, has been appointed to succeed him.——Dr. Romeo R. Stevenson, Sioux Falls, has returned from a six months' trip to Europe.

Law Constitutional But Not Retroactive.—Dr. Gilbert Loeffler, Yankton, who was arrested a short time ago by the authorities of Minnehaha County on the charge of having come to the county to practice without having paid the $500 itinerant physician's license required by the medical examiner law of the last legislature, has been discharged. Judge Jones held that the law does not apply to physicians who were practicing in the state when the law went into effect July 1, 1903. The decision in no way affects the constitutionality of the law.

GENERAL.

Yellow Fever in Mexico.—No particular change is reported in the yellow fever situation in Mexico. Considerable financial loss is reported from Texas cities, due to the interruption of commerce.

Queen's Hospital, Hawaii, Report.—The biennial meeting of the Queen's Hospital Corporation, Honolulu, was held August 20. The number of patients admitted in 24 months was 1,398, of whom 522 were Hawaiians, 232 Americans, 165 Portuguese, etc. There were 95 major and 128 minor operations; and 92 deaths, which was a percentage of 6.28 per cent. Under agreement with the U. S. Public Health and Marine-Hospital Service 237 American seamen, of whom 41 were Hawaiian born, were admitted, and were treated by marine-hospital surgeons.

An Impostor.—Dr. J. H. Musser, Philadelphia, wishes to warn the profession concerning a young man who pretends to be his nephew, and on various pretexts secures money—mostly from Dr. Musser's personal friends. Dr. Musser has no nephew by the name of Musser, and knows of no one who dares use his name in any scheme whatever. Mr. P. Corzelius, representing the American Medical Association, has a letter from Dr. Musser, as well as other means of identity for the purpose of carrying on his work. Dr. Musser wishes other journals to circulate this warning.

Eddyism in Hawaii.—Hawaiian sorcerers and witch-doctors have taken up Eddyism and find it right along their line. At-

tention has been called to this by the recent death of a sick man from being beaten on the head with a heavy bible. A native by the name of Makaio has been sentenced to a term of two years for manslaughter, for prescribing the above treatment. He alleged that he directed simply the placing of the bible on the man. The widow alleged that he directed the more vigorous application, which she gave. His description of his satisfaction with Eddyism as a treatment is interesting.

The Cuban Plague Scare: Is It Yellow Fever?—The alleged disease at Daiquiri, near Santiago, Cuba, continues to cause much remark in the lay press. The latest development is the assertion of Dr. A. M. Fernandez Ybarra, who has recently come from Cuba, that yellow fever exists in Cuba, and is kept secret by the officials to prevent the United States from stepping in and establishing a quarantine, as is agreed by the treaty in case of an epidemic of yellow fever. He alleges that cases of yellow fever are called remittent fever, pernicious malarial fever, malignant jaundice, etc. In reply to this assertion, the United States Public Health and Marine-Hospital Service denies the presence of yellow fever, and declares that the statements of Dr. Ybarra are based on misinformation.

CANADA.

Spitting in Montreal.—The Woman's Christian Association of Montreal is making strenuous efforts to prevent spitting in the streets of that city. A deputation of the members waited on the mayor last week and presented statistics showing the prevalence of the habit.

Ontario Board of Health.—The Ontario government has appointed the following to compose the Ontario Board of Health for the next three years: Dr. Edward E. Kitchen, St. George, chairman; Dr. Alexander Thompson, Strathroy; Dr. R. P. Boucher, Peterboro; Dr. Wm. H. Oldright, Toronto; Dr. John Douglass, Coburg; Dr. J. J. Cassidy, Toronto.

St. Francis District Medical Association of the eastern townships of Quebec held its annual meeting at Sherbrooke, September 10. The election of officers resulted as follows: President, Dr. L. C. Bachaud; vice-presidents, Drs. J. McCabe and A. J. Beique; secretary, Dr. F. A. Gadbois; assistant secretary, Dr. Williams; council, Drs. Farrell, Austin and Carmichael.

Canned Vegetables Analyzed.—The chemists of the Inland Revenue Department at Ottawa have just completed an analysis of 100 samples of canned vegetables. No chemical preservative was detected in any sample. All save two were found in good condition. In two instances copper was found in peas, but only a trace, and there was no evidence that it was put there for the purpose of intensifying color.

Much Typhoid.—The report for August of the Montreal General Hospital shows that 243 patients were admitted into the wards during that month, that 217 were discharged and that 18 died. A great increase in the number of typhoid fever cases was reported, the capacity of the institution being severely taxed. At one time there were 55 cases, as compared with 15 in the corresponding month of 1902. In the out-door department there were 2,904 consultations. In July there were 280 patients and 21 deaths.

Executive Health Officers of Ontario.—The eighteenth annual meeting of the Association of Executive Health Officers of Ontario was held at Peterboro, September 9 and 10, under the presidency of Dr. Thomas MacFarlane of Ottawa, chief analyst for the dominion government. A discussion took place on a paper submitted by Dr. W. T. Connell, professor of pathology in Queen's University, on "A Water-Borne Epidemic of Typhoid Fever," and on a paper read by Dr. McNulty of Peterboro on "The Etiology and Suppression of Typhoid Epidemics." Another paper which excited keen discussion was one by Dr. Shaw of Keene on "The County Medical Health Officer," showing that there was a general feeling favoring a change that would substitute county and district health officers for township officers. A resolution was passed instructing the executive committee of the association to bring to the attention of the provincial government the necessity of some form of military drill being introduced into the public schools of the province. The election of officers resulted as follows: President, Dr. J. W. Lane, Mallorytown; vice-president, Dr. C. A. Bowlby, London; secretary, Dr. Hodgetts, Toronto; executive council, Dr. P. H. Bryce, Toronto; W. Chipman, C.E. Toronto; Dr. J. M. Shaw, Keene; Mr. W. S. Richards, Chatham, and Dr. Boucher, Peterboro.

FOREIGN.

Typhus in China.—A severe epidemic of typhus is reported (via Pekin) in the interior of China. Ten thousand persons have died.

Thousands for Roman Sanitarium.—Signor Pietro Cartoni, a rich Italian farmer, has given $190,000 for a tuberculosis sanitarium outside the city of Rome.

Biologic Blood Test Officially Adopted in Vienna.—The institute for serotherapy connected with the Vienna University has been empowered to furnish prepared serum for the biologic blood test for medicolegal testimony.

Statue to Ollier.—The model has been completed for the bronze statue of the late Professor Ollier which is to be erected in some public square in Lyons. There is to be only the life-size figure of the surgeon in his robe, on a simple granite pedestal.

Australia Wants Good Food for the Army.—A law has been passed in Australia, prescribing a penalty of three years' hard labor for supplying or knowingly receiving supplies for the army inferior to specifications. This includes contractors or purveyors and officials of the army supervising such matters.

Von Behring Honored.—The Emperor of Germany has conferred the title of *Wirklicher Geheimer Rath*, or actual privy councilor, on Prof. E. von Behring—a rare distinction. It is the first time that it has been given to a member of the profession who has not gained eminence as a surgeon, as was the case with Esmarch and von Bergmann.

Plague in Marseilles.—Eleven cases of bubonic plague with seven deaths occurred in Marseilles, France, the first of this month. They originated from a steamer with a cargo of rags from Constantinople. Prompt disinfection was enforced and the spread of the plague, it is thought, has been prevented. Cable reports state that there is little doubt of the identity of the plague.

Reduction of Lead-Poisoning in Germany.—The hospital statistics for Prussia show that the number of persons treated for lead-poisoning has fallen from 1,624 in 1899 to 1,383 in 1901. The total number of male patients admitted to the hospitals has increased during this time from 371,378 to 502,113, showing that the reduction in the cases of lead-poisoning is a reality.

Investigation of Substances Producing Radium.—The Vienna Academy of Sciences has appointed a committee, which is already at work, studying the pitchblende, the substance from which radium is derived. It occurs in profusion in the mineral-bearing mountains of Bohemia. Baron Auer von Welsbach, whose name is so familiar to Americans, has placed his extensive works and laboratories at the disposal of the committee.

The Next French Congress of Alienists and Neurologists.—The thirteenth congress was held at Brussels as previously mentioned. An interesting feature of the meeting was the trip to the family colony at Gheel, which has been in operation for centuries and is always cited by advocates of the family colony plan. The next congress will be held at Pau in August, 1904. Brissaud will preside and the following questions have been appointed for discussion; Organic Dementia; Motor Localization in the Cord, and the Criminal Insane.

Remuneration for Contract Practice in Germany.—The official sickness insurance societies of Saxony have recently published their annual report. It shows that the 2,463 societies in the kingdom paid for medical attendance during 1899, 4,867,008 marks, or about $1,234,000, equal to 4.25 marks, or $1.06 per member. This is an increase of 22 cents per member during the last five years. About 21.75 per cent. of the total income of the societies is paid out for medical attendance. These figures are above the average, and are regarded as an instance of benefit derived from organization of the profession.

Attempt at Suicide with Typhoid Cultures.—A young woman who had access to the medical laboratory connected with the Paris Charité hospital took from the incubator two tubes containing virulent cultures of the typhoid bacillus and swallowed the contents. The case is described in the last *Archives Gén. de Méd.* as a laboratory experiment demonstrating with mathematical exactness the data that have been gleaned from experimental research and by observation at the bedside. There were no symptoms for two days, then violent headache and by the sixth day the patient could not leave her bed. The temperature began to rise the seventh day, and after this the typhoid fever ran the customary course. She recovered in due time, and four months later was delivered of a living child.

The Leipsic "Verband."—This is the abbreviated name by which the German Association for the Relief of the Economic Conditions of Members of the Medical Profession is known in Germany. It was founded only a few years ago to supply advice and material aid to physicians struggling to maintain

their independence in contract practice or under other disadvantages. The Verband has aided the medical officers of the sickness insurance societies at Gera, Mühlhausen and elsewhere and warned other physicians not to take the places resigned by the officers on account of the intolerable conditions prevailing. The recent legislation on sickness insurance has brought numbers of new recruits into the association until it now has 8,933 members. At present it has seven places on its list where it is assisting the physicians, both materially and morally, in their resistance to the degradation of the profession by the sickness insurance societies. At Constance troubles of this nature have just been satisfactorily settled, thanks to its mediation.

Denunciations of Pasteur Treatment of Hydrophobia in Italy.—The *Journal de Méd. de Paris* never misses an opportunity to cast discredit on Pasteur treatment, and, in fact, Lutaud, the editor, has never accepted the science of bacteriology with the same seriousness as the rest of the medical world. The last issue of that journal contains a letter from Dr. C. Ruata, professor of hygiene at Perugia, commenting on the recent death of 4 persons at Novara who had been bitten by a rabid dog and who had taken a course of treatment at the Pasteur Institute at Milan. Ruata's communication also appears in certain Italian papers. He asserts that since the Pasteur institutes have been introduced into Italy the number of deaths from hydrophobia has constantly increased, whereas they used to average 65 a year, during the last fourteen years, since the institutes were organized, the average has risen to 85. About 3,000 persons are treated each year in the nine institutes in Italy, and the number of deaths has risen by a third. He argues that this state of things should be changed and prophylactic hygienic measures adopted instead of the false security imparted by the Pasteur institutes. The patients whom they report as cured probably never had the disease and would have remained in better health without it. Lutaud comments on the letter that Ruata's words will certainly attract attention where "science is not hypnotized by the glory of the gr-r-r-reat Pasteur."

Correspondence.

Tetanus in the South at the Christmas Celebration.

SAN ANTONIO, TEX., Sept. 9, 1903.

To the Editor:—Reading the editorial in THE JOURNAL, August 29, giving the astounding number of the last Fourth of July tetanus cases, it occurred to me to call your attention to the fact that the number of tetanus victims of the blank cartridge will be much greater if you include those which result during the Christmas celebration in the south.

On my arrival from the north to this city about four years ago I was pleasantly surprised to find how orderly and quietly the people here celebrate the Fourth of July. Not a single accident case was reported in the press; but my surprise was still greater when Christmas day came: Fire crackers, pistols and cannons were all brought into use in trying to make up for the Fourth of July. The celebration is in part kept up till after the New Year's day, and certainly, the usual accidents followed by tetanus are not wanting. The last Christmas celebration carried off two victims of tetanus, to my knowledge: a colored boy of 8 and a young white girl of 16. I am told that the same sort of Christmas celebration is going on all over the south. How far this is true, I think it will be worth while for you to investigate.

R. ROBINSON, M.D.

Sawing Off a Plaster Cast.

OAKLAND, CAL., Sept. 7, 1903.

To the Editor:—In THE JOURNAL, September 5, Dr. Bechtol speaks under New Appliances of the Gigli saw in the removal of plaster-of-paris casts, and describes the method. Whenever I think I have discovered something new I always think of the saying, "Go abroad, young man." The method and saw described have been in use several years on this coast. One of the first *x*-ray photographs taken in the Waldeck Hospital about seven years ago shows the saw in the cast, as it was left under the cast until the plaster had set; which is better than removing it while the plaster is wet and soft. If not the Gigli saw, a piece of twisted or nicked steel wire will do. It is well to put on a light gauze bandage over the cotton before covering up the wire with the plaster, because if the cotton catches in the wire it will not work. Put vaselin on the wire or it will get rusty and break easily if you should leave it in over night.

The idea is all right when one is sawing over a concave surface, but when sawing over a convexity the saw is liable to seek the level of the two resisting ends and cut anything that presses along its route. The saw is working in the dark, as it were. After the Doctor has sawed down on a few patellas and malleoli, and cut open the back of the leg a few times, and spoiled a few dollar and a half Gigli saws, he may resort to the old-fashioned ten-cent cobbler's knife which every one knows how to use and has no attachments. By filing it so as to get a rough wire edge and running it over the dressing just before it sets, it will cut easily, and you know what you are cutting. If you have a compound fracture and want a window in your dressing the saws are useless.

M. LEWIS EMERSON, M.D.

Illegally Reprinting Articles from the Journal.

NEW YORK, Aug. 18, 1903.

To the Editor:—My attention has been called to a reprint of my article on "Anesthol" (which appeared in THE JOURNAL, Feb. 28 and March 7, 1903), made and circulated by Messrs. Lehn & Fink, a wholesale drug firm of New York. These reprints were made entirely without my knowledge. I promptly wrote to Messrs. Lehn & Fink, asking for an explanation. The answer I received from them was most unsatisfactory, carefully avoiding the point at issue: "lack of my (the author's) consent for making the reprints," and not even offering an apology for their conduct.

I can but protest against the method adopted by this firm, viz., using a scientific article for commercial purposes, without securing the writer's consent prior to their doing so. I need not assure you that had they asked me beforehand I would have refused their proposition most emphatically. Is there no way of protecting a professional man against such abuses? WILLY MEYER.

NOTE.—Everything printed in THE JOURNAL of the American Medical Association is copyrighted, and no one has a right to reprint any of its contents without permission, consequently, Lehn & Fink are liable to prosecution for violating the copyright laws. It is to prevent just such occurrences as this that THE JOURNAL goes to the expense of copyrighting all of its contents, and such a violation of law and the rights and privileges of others, we are happy to say, seldom occurs.

The Proper Perineal Prostatectomy Incision.

GLASGOW, Aug. 29, 1903.

To the Editor:—The incision in question is undoubtedly the inverted Y, as advocated by Professor Senn in THE JOURNAL, August 15, and there can be little doubt that its more general acceptance will be hastened by the support its practice has just secured at the hands of an authority so widely accepted as Professor Senn's.

The inverted Y incision I have practiced and taught for years as the proper incision for perineal prostatectomy. Among the earliest of my references to it may be noted a description of it in a paper on prostatectomy in the *Lancet*, April 14, 1894, and in a discussion in the New York Academy of Medicine (reported in the *Medical News*, 1898) it was subjected to just such unfavorable criticism as Professor Senn now seeks to disarm, and which, though coming from other quarters as well, has never affected my belief in its merits. I rarely make use of any other. JAS. H. NICOLL,

Professor of Surgery, Andersonian College, Glasgow.

The Lust of Slander.

ROSELLE, ILL., Sept. 14, 1903.

To the Editor:—In possible explanation of the "Leffingwell accusation," referred to in your editorial, "The Lust of

Slander," in THE JOURNAL, September 12, permit me to suggest that Leffingwell has made to serve his purpose a statement which, in itself true and authenticated, does in no wise refer to vivisectors and their work. Krafft-Ebing, in his "Psychopathia Sexualis," page 84 et seq., says, in discussing sadism:

In numerous cases, sadistically perverse men, that are afraid of criminal acts with human beings, or that care only for the sight of the suffering of a sensitive being, make use of the sight of dying animals, or torture animals, to stimulate or excite their lust. (Then follow some cases.) Thus, in these and similar cases, the vita sexualis is so constituted, *ab origine*, that the sight of blood, death, etc., excites lustful feeling.

I think it very probable that Leffingwell has used the above quotation for his purpose. The fact that it does not at all serve, except through the lie, and that the whole argument is "*an den Haaren herbei gezogen*," has troubled him but little.

H. J. ACHARD.

The Physiologic Generation Cycle of Woman.

MAHANOY CITY, PA., Sept. 9, 1903.

To the Editor:—In THE JOURNAL, September 5, page 627, synopsis of Dr. Jennie G. Drennan's paper on the "Physiologic Generation Cycle of Woman," the following statement is made:

In mammals and primitive woman ovulation occurs at distinct periods of the year and at no other time. Mating with the primitive woman was much like that of the brute creation now; as soon as she was sexually mature she married and entered on the physiologic cycle of a mammal, etc.

It has seemed to me in the course of my studies that ovulation depended more on the abundance of food at the command of woman than any other cause, regardless of the stage at which she lived in the history of civilization. I wish Dr. Drennan would state the grounds on which she bases her statement, for it is a very interesting scientific fact if primitive woman differs so radically from her sister in civilization.

GEO. W. REESE.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

LIMITS OF CONSANGUINEOUS MARRIAGES.

———, ——., Sept. 12, 1903.

To the Editor:—Will you kindly inform me through the "Queries and Minor Notes" whether the offspring from the marriage of second cousins are generally considered beyond the defects and deformities resulting from consanguinity? If not, what per cent. are considered so afflicted? E. G. B.

ANS.—A second cousin has only half the common heredity of a first cousin. According to Galton's calculation, their respective amounts can be represented by 1/8 and 1/16; therefore, the chances of morbid heredity would not be more than one-half, probably less. There has been no legislation against the marriage of second cousins anywhere, so far as we know, and we believe such marriages are generally considered comparatively safe as regards offspring. Still, in special cases, there might be a concentration of the common heredity even beyond this degree of relationship. As to in what percentage of cases this would occur, we know of no way of determining.

CONDUCT AFTER SALE OF PRACTICE AND SUPPOSED PERMANENT REMOVAL.

CITY OF MEXICO, Aug. 21, 1903.

To the Editor:—Please publish your opinion of the ethics of the following case: Three years ago A hired B to go to a foreign country, where A was established, and assist him. B was to have a salary the first year and a third interest in the business the second year. At the beginning of the second year B prefers an increased salary to the third interest, and is accommodated, but still claims the right to the third interest at the end of the second year. This is agreed to. During the second year B becomes dissatisfied on account of ill health, and desires to return to the United States. A induces C to purchase the interest of B in the business, which he does, paying therefor $1,000, which B accepts and immediately returns to the United States, having previously introduced C to as many of his patrons as the time permitted. No contract or papers were signed. B returns in a few months and resumes independent practice, claiming that he has a right to do so. Did he act honorably? X. Y. Z.

ANS.—To the *ex parte* statement made by our inquirer, there can be but one answer, and that is that B did not act honorably, to say the least. Furthermore, there certainly is redress for C if he should go to law. C paid $1,000 for B's practice and good will, which meant that B must give up his practice and good will. By his returning and entering into practice again, he took back the two things that he sold. He should, therefore, give back the $1,000.

RIGORS IN TYPHOID WITH HIGH TEMPERATURE.

AMERICUS, GA., Aug. 31, 1903.

To the Editor:—In typhoid fever, characterized by high temperature, rigors occur when the temperature is the highest. These rigors are not due to malaria; the patient will have them when thoroughly cinchonized. Can you give me the cause of this?

J. C. FIELD, M.D.

ANS.—In typhoid, chills occasionally occur where no clear explanation of their cause can be offered. Perhaps the most frequent time of the occurrence of severe chills is during convalescence, when there may be repeated rigors. Why this is so is not plain. Of course, chills at the onset are not so very unusual. And complications, such as pneumonia, parotitis, malaria or secondary infection with pyogenic organisms, may be ushered in by a chill, and where antipyrin, acetanilid or phenacetin have been used with a free hand chills are not infrequent. Perhaps the chills that occur during the course of the disease are at times due to the sudden invasion of the blood by unusually large numbers of typhoid bacilli, or the unusually rapid development of the germs within the blood. Complications that are often unrecognizable, as in the mesenteric glands or gall bladder, may explain them at times. Constipation, with its attendant absorptive toxemia, is held by some to be the cause of some of the chills of typhoid fever. Until more is known of the real physics and chemistry of chill production in general, some of the chills of typhoid must go unexplained. Certainly, in the cases mentioned by our correspondent, malaria is ruled out as a cause, for not only does malaria, when it complicates typhoid, usually manifest itself during convalescence, but it will not resist quinin if freely given.

A full discussion of the subject of chills in typhoid fever will be found in Osler's "Studies on Typhoid Fever," Series II, in the Johns Hopkins Hospital Reports, Vol. IV, and in Vol. VIII, p. 443, et seq. See, also, the recent article by Dr. Delafield in the *Medical Record*, September 12, on "Post-typhoid Sepsis," abstracted in our next issue.

Miscellany.

Information Wanted of a Fraudulent Agent.—Dr. W. H. Snyder, who recently reported a fraudulent solicitor for *Colliers' Weekly*, reports that Mr. L. H. Bortner, the local manager for Collier, called and fulfilled the contract, although they did not receive the money. Mr. Bortner, whose address is 50 Law Building, Toledo, Ohio, wishes information of any other physician who subscribed with this agent or information as to the agent's whereabouts.

Marriages.

JAMES INGERSOLL WERNHAM, M.D., to Miss Winifred Patrick, both of Marengo, Ill., September 9.

OSCAR L. FULLERTON, M.D., Redding, Iowa, to Miss Eva L. Johnson of Neva, Mo., September 2.

CLIFTON MEREDITH MILLER, M.D., Richmond, Va., to Miss Mary Ashley Bell of Fluvanna County, Va., at Wilmington, Va., September 3.

JAMES V. CORNISH, M.D., Quincy, Ill., to Miss Lettie S. McConnell of Ellington Township, Adams County, Ill., September 6.

Deaths.

Charles F. W. Myers, M.D. College of Physicians and Surgeons, New York, 1874, a member of the American Medical Association; lieutenant colonel and medical director, N. G., N. J., and a member of the Association of Military Surgeons of the United States, who had been in ill health for several years, died August 31, from apoplexy, at his home in Paterson, N. J., aged 54.

Nelson V. Prewitt, M.D. University of Virginia, Charlottesville, 1893, of Winchester, Ky., a member of the Clark County Medical Society, Kentucky Valley Medical Association, Kentucky State Medical Association and the American Medical

Association, died at St. Joseph's Hospital, Lexington, Ky., September 1, 36 hours after an operation for appendicitis, aged 32.

William Cary Barrett, M.D. University of Buffalo, N. Y., 1880, dean of the dental department of the University of Buffalo, oral surgeon at the Buffalo General Hospital and eminent as a practitioner and teacher of dental surgery and pathology, died at Bad-Nauheim, Germany, August 22, from heart disease after an illness of a year, aged 69.

K. O. Austin, M.D. College of Physicians and Surgeons of Chicago, 1896, was found dead in his office in Chicago, September 7, aged 38. The coroner's jury found that deceased had taken hydrocyanic acid with suicidal intent while laboring under great mental depression following determined attempts to rid himself of his craving for morphin.

Harry De Haven Cameron, M.D. College of Physicians and Surgeons, New York, 1889, of Brooklyn, and surgeon of Troop C, N. G., N. Y., who served during the Spanish-American War in Porto Rico, died from consumption, September 4, at Pony, Mont., after a long illness, aged 37.

William T. Dalby, M.D. Omaha Medical College, 1885, health commissioner of Salt Lake City for four years, and local surgeon of the Union Pacific Railway, died at his home in Salt Lake City, September 7, from cancer of the stomach, after a lingering illness, aged 44.

Jesse C. Pfaffer, M.D. Medico-Chirurgical College, Philadelphia, 1902, interne in charge of the orthopedic department of the Medico-Chirurgical Hospital, died at St. Joseph's Hospital, Philadelphia, September 6, from typhoid fever after an illness of ten days, aged 22.

Emily R. Robbins, M.D. Penn Medical University, Philadelphia, 1857, said to have been the first woman to obtain a medical diploma in America, died at her home in Philadelphia, September 1, aged 71.

Henry S. Cunningham, M.D. Starling Medical College, Columbus, 1865, for twenty-five years a resident of Indianapolis, died, at his home in Alva, Okla., September 5, after an illness of five years, aged 64.

James A. Mawris, M.D. Albany (N. Y.) Medical College, 1853, surgeon of the 178th New York Volunteer Infantry in the Civil War, died at his home in Lafayette, N. Y., September 2, aged 78.

Alonzo Richardson Morgan, M.D. Homeopathic Medical College, Philadelphia, 1852, of Waterbury, Conn., died at the Massachusetts Homeopathic Hospital, Boston, August 31, aged 73.

J. T. Walpole Kerns, M.D. Marion-Sims College of Medicine, St. Louis, 1892, died at his home in Bellaire, Ohio, September 8, from Bright's disease, after an illness of two months, aged 62.

Quincy J. Winsor, M.D. Western Reserve University, Cleveland, 1884, was found dead at his home in Cleveland, September 7, from asphyxiation by gas, or heart disease, aged 40.

John M. Kitchens, M.D. Medical College of Alabama, Mobile, 1885, died at his home in Hartsells, August 30, from tuberculosis of the liver, after an illness of eight weeks, aged 50.

Henry S. Ballou, M.D. Bellevue Hospital Medical College, New York, 1880, died at his home in Monument, Colo., September 1, from eczema, after an illness of fourteen weeks, aged 55.

Luis P. Walton, M.D. College of Physicians and Surgeons, New York, 1870, of New York City, died suddenly from heart disease at the Bath Club, London, Eng., September 8.

James C. Clark, M.D. Atlanta (Ga.) Medical College, 1873, died at his home in Covington, Ga., September 7, after an illness of six weeks, from typhoid fever, aged 54.

Samuel C. Cravens, M.D. Rush Medical College, Chicago, 1866, died at his home in Bloomfield, Ind., September 5, from paralysis, after an illness of two days, aged 64.

Orville C. Bordwell, M.D. Eclectic Medical Institute, Cincinnati, died at Newfane, Ohio, August 29, aged 71.

Deaths Abroad.

Joseph Schnetter, M.D. University of Würzburg, Germany, for forty years a practitioner of New York City, but later a resident of Karlsruhe, Germany, died at Herrenalb, Black Forest, August 16, aged 81.

John Thomas Griffith, M.D. St. Andrews, Scotland, 1859; F.R.C.S. Eng., 1850; M.R.C.S., 1845; L.S.A., 1849, for more than thirty years a practitioner of London, and a civil surgeon in the South African campaign, died recently at Weybridge, Surrey, from paralysis, aged 82.

Association News.

The Prize Essay of the American Medical Association.

A gold medal, value $100, is offered annually by the American Medical Association for the best essay on any subject relating to medicine or surgery. The successful contestant for this prize may choose to receive either, 1, the gold medal, or 2, a bronze replica of the medal and the remainder of the appropriation (about $90) in money; or 3, the entire amount ($100) in money. Since the Association annually sets apart the sum of $500 for original research, this prize is offered to stimulate the production of a superior practical essay based either on experimental studies or clinical investigation or both. The committee will give preference to essays having the greatest brevity consistent with thorough consideration of the subject, and recommends that essays shall not exceed 5,000 words. The committee, while not restricting the choice of subjects, recommends as an important subject for consideration: "The Therapeutic Value of the Digestive Ferments." Competing essays must be typewritten and must bear no mark revealing their authorship; but instead of the name of the author there must appear on each essay a motto and accompanying each essay must be sent a sealed envelope containing the name of the author and bearing on its outer surface the motto of identification. No envelope will be opened by the committee until a decision has been reached as to the most deserving essay. The other essays will be returned to their respective authors. The committee reserves the right to reject all essays if none are found worthy of the Association medal. Competing essays must be in the hands of the chairman of the committee not later than April 1, 1904.

Committee: LEWIS S. MCMURTRY, Louisville, Ky., Chairman; BURNSIDE FOSTER, St. Paul; M. H. FUSSELL, Philadelphia.

Medical Organization.

MEDICAL ORGANIZATION METHODS AND BENEFITS.

J. N. M'CORMACK.

(*Concluded from page 677.*)

ADMISSION OF FORMER SECTARIANS.

Under the present plan of organization this is a question which each county society must decide for itself. It is a question, too, about which there is room for honest difference of opinion. The habits of thought and prejudices of a lifetime can not be overcome in a day, even though conditions causing them have largely disappeared. There need be no haste about it, and with the element of time, and an abundance of good temper on all sides, a fair and just consideration of the rights and interests of all concerned can be secured. As a matter of expediency it will usually be better not to invite persons about whom there is likely to be any dispute to the initial meeting. Their presence might interfere with the free consideration of the subject which its importance demands, or some injudicious person on either side might give or take offense. After the society is organized it can decide whether or not it will consider the matter then, refer it to a committe to report at some future meeting, or postpone it indefinitely. It will be found that the objections to the admission of these people are usually founded on a misconception of the provisions for it made in the by-laws. If legally registered and otherwise reputable, they are entitled to membership on condition that they have or will sever their connection with all sectarian organizations, and come to us as citizens, not aliens. When so elected they are no longer homeopaths or eclectics, but are promoted to be plain physicians, like the other of us. Many of them are entirely worthy of admission. It will be found that most of them became sectarians by chance, as it were, and attended college and graduated before they really knew anything of sects or systems of medicine. Most of them have been broadened by actual experience until they differ from us in views and methods as little as we differ from each other, and have long been homeopaths or eclectics only in name. Many of them are recognized as physicians of ability, and as powers for good in the community, and if they are willing to

meet the conditions of our invitation, made fair and honorable for them and us, and come into an organization in which they are hopelessly outnumbered, there seems every reason for accepting them, especially as in most sections they are so few in numbers as to be cut off from any society unless they join ours. It is due all concerned that this whole matter should be dealt with in a spirit of the utmost frankness and kindness, so that a suggestion made in the interest of harmony may not, by either accident or design, be turned into an apple of discord. In this connection it may be said that two inquiries have been received as to osteopaths. This is a passing fad which has about settled itself. They do not claim to be physicians and should not be so considered anywhere.

CROOKED STICKS.

In a like way may come up the question of the advisability of admitting to membership those who have been more or less unethical and off color in the past. Each case of this kind will have to be considered and decided on its merits, but it should be done on liberal lines. In a county where no organization worthy of the name existed, and where each physician has been forced to decide all the nice questions of professional conduct as they arose on his individual and untrained judgment, this important part of medical education having been entirely neglected in all our colleges, it will usually be found that there is no well-defined borderland between correct and incorrect methods except on the part of those governed by native gentlemanly instincts. It will often be found that lack of courtesy, or more or less vicious unprofessional methods, have been handed down in both town and country from generation to generation of physicians, and that those now in practice there are largely the victims of this inheritance. In all of these matters, as in the consideration of the sectarian problem, the profession is confronted by a condition, not a theory. Legally and in the public estimation these men are physicians and the profession is held responsible for them whether it will or not. Most of them are not bad men. These things being true, it will be better to give all who will come in a cordial welcome, and for a united profession, kindly and in good faith, to encourage every effort they can be induced to make to refrain from methods into which they drifted through lack of training and environment for which they are not personally responsible. In regard to the whole subject of the admission of members, and still more of their treatment after admission, it should be urged that a spirit of conciliation be substituted for the old one of suspicion, selfishness and ostracism.

In handling all of these questions, and those concerned and affected by them, as in the discharge of all of his duties, the councilor will find constant need for a fair knowledge of human nature, especially as modified in the genus homo medicus, tact, sound judgment, and never-failing good temper.

THE MEETING AND ADDRESS.

His audience selected and assembled, the councilor should proceed with his address, beginning usually with a brief history of the origin and progress of the reorganization movement. The importance of the county societies, their relations to the state association, and the necessity for coincident membership in both, and for the support of the state association as a bond of union and agency for concentrating and carrying out the views of the profession of the state in all matters of public concern, should be fully explained. In a like way the connection of the state organization with the American Medical Association, and the privilege which each one joining his county society has of membership in the national body, should also be fully explained. They should be advised that a full return for the membership fees in all these bodies will be received from their periodicals, to say nothing of the other advantages. The monthly bulletin or journal, or the annual volume of transactions of the state association will be sent free to all members, and the great weekly, THE JOURNAL of the American Medical Association, will go free to all who join that body. The value of these publications in all this work is so great that pains should be taken to make their relation to the membership clear. They all belong to the profession, and it alone receives the profits of their publication. This is as true of THE JOURNAL of the Association as of the state journals. Aside from the desire they have to discharge all the duties of their respective positions, and the justifiable pride they feel in its great success, the Board of Trustees, the Editor and the other officers have no more stock or interest in THE JOURNAL than the humblest member. For these reasons, and because of the many benefits they will receive from it, each of them should be advised to obtain full membership in all these bodies, and blanks should be furnished the secretary for this purpose.

Having made the plan, purposes and privileges of the system of organization plain, he should then take up and deal kindly, but frankly and unsparingly, with existing evils, and their causes and results, in a general way, putting his discussion of these, and of the attainments and possibilities of the profession through union and co-operation in each community, on such a high plane as will make their local dissensions appear very insignificant. The advantages it will bring to them individually—scientific, social and material—the desirable and deserved position it will give the profession in public estimation, as well as the assistance it will give in securing and enforcing needed health and medical legislation, should be dwelt on.

He should also urge that just as the efforts and success of each county society will determine the results of this reform, so the character of the individual physician, each of those present, is to be the potent factor on which the efficiency and standing of that society will depend. It should be represented that no chain can be stronger than its weakest link, and the qualifications and accomplishments which each ought to strive for as a member of a great profession to which he is responsible, and which is equally responsible for him, should be earnestly put before them. It should be insisted that above all things the physician should be the cleanest man in the community in the best sense. He should be the cleanest man physically, because this is of importance in the practice of modern medicine, and a necessity in surgery and obstetrics. A slovenly doctor with soiled clothes, hands and nails is a constant menace. He should be a clean man morally, because he comes into such relations and confidences with families, and especially with young people, as to demand it. He should be the best supported man in his community, because he can not otherwise keep up the education and equipment essential alike to his own reputation and the well-being of the community, and because he is the hardest worked man in it. The lawyer, the banker, the merchant and the laborer go home after a day of toil to a night of rest, but the physician's work, like Joan's, is never done. His home should be a center of refinement and culture, and he should be a well-informed man outside of his profession, an authority on general scientific subjects, or a specialist in some attractive by-science, not only because he represents a learned profession, but because of the mental relief, breadth and power it would give him. In a word, he should be the educated, refined, courteous gentleman whom the best fathers and mothers would chose as an advisor and model for their sons. The qualifications and accomplishments which go to make a gentleman are not possible to all men, on account of inherited or other defects, but if by association and encouragement these can be induced to imitate gentlemen, so far as possible, it will be a great gain for them, the profession and the community.

ORGANIZATION OF THE SOCIETY.

At the conclusion of his address, unless some other arrangement seems more desirable, it will usually be well for the councilor to preside temporarily, and to call for a general discussion of the subject, indicating some suitable person to open it. If an organization is decided on, a good committee should be selected by those present to nominate the officers. Much will depend on the choice of the first officers, and they should not usually be named in open meeting. The secretary especially should be an active, tactful man, living at or near the county seat. The delegate to the state association should be a broad, representative man, who will attend and give his time to the

duties of his office. Following the report of the committee and the election of officers, the constitution and by-laws should be considered and adopted. If possible, the councilor should exhibit the card index outfit for county societies, and instruct the new secretary as to the method of keeping it and its far-reaching purposes. The dues for the county and state societies should always be collected from charter members by the secretary on the day of organization, and from new members when they apply, and the charter should be applied for at once. The best methods for bringing in any physicians in the county who are not present, and for meeting any difficulties likely to arise in making the society a success, should be inquired into while the councilor is present to give the benefit of his experience. Before final adjournment, the program should be arranged for the next meeting, which should always include a lunch, or refreshments in some form, to follow some interesting scientific work. If possible, the councilor should arrange to be present at some future meeting, and to keep in touch and be at the service of the society for any help he can give them. In this connection it should be said that in several states the council has called for volunteers and published a list of leading men distributed over the state or on the border of adjoining states, who will go on invitation and give their assistance to any county society within reach of them. This can easily be made of great assistance to new county societies if experienced and unselfish selections are made, and the plan is suggested for careful consideration.

SMALL AND SPARSELY SETTLED COUNTIES.

To most physicians the glamor of numbers, of a crowd, of elaborate papers and sonorous discussions, is always associated with the idea of a successful medical society. Next to the conviction that physicians can not live together in peace, it will be the most difficult of the misconceptions councilors will have to combat. Yet nothing could be further from the truth. The New York Obstetrical Society, one of the most famous and useful of the older organizations in this country, was limited by its charter to fifteen members. When five, eight or ten congenial medical spirits get together and fail to have an interesting and instructive meeting it is not the fault of those who are absent. One of the most useful societies the writer has ever known was organized by him on a chance visit in a county containing but four physicians. They were torn by the usual wrangles and dissensions, and the profession was at a low ebb. Three of them were comparatively young men, and after getting together in their society, and understanding each other, one after the other in turn went away for post-graduate work, the others dividing his work and giving him the proceeds. One of them had a taste and ability for surgery, and by an equitable and satisfactory arrangement he did that part of the practice, which had formerly been sent away or been done by surgeons called from a distance, at far greater expense and probably no better results, or more frequently the cases were left to suffer and die without attempt at relief. Under better business methods a large element in the community which had found it cheaper to change physicians than to settle their accounts, although abundantly able to do so, were induced to contribute their part to such a support of the profession as enabled its members to qualify and equip themselves for the benefit of these as well as their more honest neighbors. This society was as much a blessing to the people of that community as to the profession, and organized and conducted in the proper spirit this will always be true. Of course, much must be left to the discretion of the councilor after he has informed himself as to the conditions by conference with the physicians in such counties, but where as many as three, four or five fairly young, live men can be found it will be better for them to get together and maintain a separate organization. If they can be made to understand it and each other it is a question whether the individual benefits will not be even greater than will come to those of the more densely populated counties. Where there are less than the number indicated, or for any reason a society can not be maintained, in counties of this kind the physicians in them should hold their membership in an adjacent strong society, or two or three such counties should be joined together in a hyphenated society, as provided in the by-laws.

COMPENSATIONS OF COUNCILORS.

At the outset it was intended to recommend that a paid organizer be employed by each state association, who could devote his entire time to the work. Owing to lack of funds and other reasons it appeared more desirable to provide for volunteer workers in smaller fields, with only their actual expenses paid, and finally the council, as an executive committee, with large discretionary powers, and with its individual members as organizers and supervisors of county societies, was the outcome. These expenses should always be paid promptly and cheerfully. As a business proposition the state associations can make no better investment. The other compensations of the councilor are large and varied. It gives him an extensive and desirable acquaintance, broadens his own mental horizon, and offers an opportunity of real good to his fellows almost beyond conception. To return to a county and find harmony and co-operation substituted for dissensions and enmity, to find that some have taken post-graduate courses, that others have taken up their studies at home, and that all, or nearly all, are united for the advancement of the profession, will be his ample reward.

HOUSE OF DELEGATES.

The duties of this body are so fully defined in the by-laws that little more need be said here. Its program should be entirely distinct from that for the general meeting, following it in the same leaflet. The first meeting of the house should be held in the afternoon of the day preceding that fixed for the annual session. By holding an afternoon and evening session then the business may usually be so advanced as to enable delegates to enjoy much of the privileges of the general meetings. Its hall should be commodious and comfortable, with convenient rooms for committees, and sufficiently remote from the general meeting as to avoid interruption from each other, should it become necessary for both bodies to be in session at the same time. At least one session should be devoted to the discussion of the health and medical laws of the state. The state board of health and the state board of medical examiners should be invited to attend and take part in this discussion with the view of securing harmony of views and concert of action in procuring and enforcing such legislation. Detailed reports should be heard as to the condition and needs of the profession in each county, from its delegate, supplemented by suggestions from the councilor of the district. To do all of this properly it may sometimes be necessary for the house to sit while the general meeting is in session on the second or third day, or to remain in session for a day after the general meeting adjourns. As this body will grow in importance and occupy more and more time with a proper discharge of its duties, no one should accept the position of delegate who will not devote himself to the work and remain until it is completed.

THE GENERAL MEETING.

The functions and purposes of the general meeting are so well understood as to require little discussion. Freed from the time-consuming distractions of all miscellaneous business, and relieved of the duty of electing the officers, it can in future devote its entire time to scientific work. The writer recently had the privilege of attending such a meeting. Under a model program, the invocation address of welcome and response were followed by the first symposium, without an intervening motion. During three days but one item of miscellaneous business was suggested, and this was referred to the house of delegates without debate. Under such an arrangement ample time was afforded for the full discussion of papers and scientific reports, the program was completed and the interest was fully sustained until the final adjournment. The majority of physicians take little or no interest in the ordinary legislative proceedings of state associations, and as soon as it is known that these parliamentary wrangles and tedious discussions are things of the past there promises to be a class of attendance and revival of interest very much to be desired.

THE CARD INDEX REGISTER.

Before the profession can be permanently organized, or as a part of such work, it is necessary to know who compose it, where they live, and the professional status and antecedents of each one. This is also necessary as the first step in purging our ranks of the dishonorable and criminal classes—the quacks—who have donned our livery for their own nefarious purposes. Experience in a few states shows that reputable physicians will gladly furnish the information of themselves if it does not involve too much trouble, and it must be had of the disreputable ones, even at much cost and trouble. The difficulties involved in this only emphasize the importance of undertaking it without further delay. As in other phases of organization, the difficulties are exaggerated, and where a live county society exists, except in the large centers of population, they are easily overcome. Once the information is obtained in regard to any individual—a quack, for instance—and a label is put on him, by a systematic exchange of cards between states he can be followed and his status and identity determined anywhere. Likewise, by the use of universal transfer cards, a reputable physician moving to another county or state is at once admitted without delay or duplication of dues.

In order to have this system uniform and economical, the Association has provided a series of cards for all county and state organizations, and has arranged for county and state outfits at wholesale net prices for the benefit of every state in the Union which desires to adopt the system. These state outfits include cabinets and all the necessary record, guide and index cards, with capacity based on the number of physicians in the state, complete and ready for use. The county outfits include a box neatly labeled for each county, with an ample supply of record and transfer cards for members and non-members, and an alphabetical index, except in counties containing large cities, where small cabinets are figured. The cost of the state outfits will vary with the number of physicians. The cost of the county outfits for less than 100 physicians will be about 50 cents each, but in order to get the benefit of these prices it will be necessary to order for all the counties in a state at one time. Fourteen states have ordered the outfits up to this time, and it is suggested that the cards for each county be filled out in the office of the secretary of the state association, arranged ready for use, and sent to the county by the councilor, or by its delegate, from the next meeting. Blanks to collect all this information, and application blanks for new members, to correspond with the record cards, are furnished by the Association to all societies at the bare cost of presswork and material.

In addition to the value of this register for organization purposes, and as a means of suppressing quackery, the Association proposes to make this officially collected and accurate information the basis for a National Medical Directory. Private individuals are now publishing incomplete and misleading directories, including the names of veterinarians, dentists, and many who do not even have as much claim to professional recognition, at a great cost to the profession. A reliable directory would have great monetary value, which legitimately belongs to the profession, and could also be made very profitable to individual members indirectly. For instance, it is proposed to publish the names of all members of their county and state organizations in bold type, with full information as to their education, society affiliations and positions of honor, while the names of non-members would be in small type, with only the year of graduation and a number to indicate the college. As such a directory would naturally, in a great measure, guide insurance and railroad companies and others in choosing between medical men, its importance to members in this one matter can be readily appreciated. It will be equally useful and important in many other ways. THE JOURNAL printing establishment is equipped for getting out such a work, and once set up the same material can be used for the national directory or for any particular state, without duplication, and any of these can be furnished to members at a minimum cost. The outside demands for such a reliable official directory would be large and the profit would go to the Association, which means to the profession, as each member has exactly the same interest in its success and funds.

CONCLUSION.

The Association plan is almost perfect in its conception, scope and purposes, and yet it is believed to be entirely practical. Changes in detail may be required as the work progresses in the various states to adapt it to changed conditions, but these can be easily made. How far its benefits are to be extended to any particular county or state must be determined by its own profession, assisted by every possible influence from the outside when needed. To say that much time and increasing effort will be required to perfect such an organization, that many obstacles will be encountered, and that individuals will fail to do their duty or obstruct the work, is only to say that the undertaking is a vast one, that the agencies relied on are finite and that it is subject to the vicissitudes attending all human endeavor. Our contention is that it is worth all the time, labor and money it will cost, and more. Ours is rapidly becoming a great science. Our leaders are among the greatest of living men. With proper ideals kept constantly before our young men, and the present facilities for attaining them unknown to any other age, and impossible even to the older men of the present generation, with harmony and cooperation made possible and encouraged everywhere, and all supported by a public confidence inevitable because it will be deserved, everything desirable will be brought within reach of the profession. The vexed problem of medical education can then be taken up with confidence and justly and wisely solved. The question of reciprocity in licensure and membership between the states can be settled on some safe and equitable basis. Provision for continuous scientific research and for systematic collective investigation into the causes and prevalence of disease can be made on the broad and generous lines demanded by the great interests involved. Constructive statesmanship can be substituted for the narrow, time-serving political methods of the present in municipal, state and national public health affairs, and our profession, united, educated and ennobled, will then occupy its rightful place as one of the greatest powers for the protection and elevation of the race.

Grundy County (Iowa) Medical Society.

Thirteen physicians of the county met at Traer, September 1, and organized a county medical society.

Ripley County (Ind.) Medical Society.

Dr. George T. MacCoy, Columbus, councilor for the Fourth District, is organizing a county medical society at Versailles.

Whitley County (Ky.) Medical Society.

Dr. Arthur T. McCormack, councilor for the Third District, announces the organization of this society, with Dr. Edwin S. Moss, Williamsburg, president; Dr. C. Garrard Ellison, Williamsburg, vice-president, and Dr. S. Sullivan, Rockholds, secretary and treasurer.

South Dakota Second District Medical Society.

In the September 5 issue of THE JOURNAL, the organization of the Codington County Medical Society was noted. This was incorrect, as the meeting was of physicians of Clark, Codington, Deuel, Grant and Hamlin counties, comprising the Second District of the state.

Catawba County (N. C.) Medical Society.

A number of physicians of the county met at Newton, September 5, and with the assistance of Dr. Thomas E. Anderson, Statesville, organized a county medical society. Dr. James R. Campbell, Newton, was elected president; Dr. W. L. Abernethy, Hickory, vice-president, and Dr. George H. West, Newton, secretary and treasurer.

Milam County (Texas) Medical Association.

Physicians of Milam County met in Cameron, September 4, and organized a county medical society with the following officers: Dr. Edward N. Shaw, Cameron, president; Dr. I. Coleman, Hanover, vice-president; Dr. I. P. Sessions, Rockdale, secretary and treasurer, and Drs. William W. Greer, Cameron; Albert S. Epperson, Cameron, and Charles W. McBurnett, Minerva, censors.

Gaston County (N. C.) Medical Society.

This society was organized at Gastonia, September 5, by State Councilor Dr. Edward C. Register, in accordance with the reorganization plan of the Medical Society of the State of North Carolina and the American Medical Association, with an initial membership of 19. The following officers were elected: President, Dr. Robert M. Reid, Gastonia; vice-president, Dr. J. Brown Wallace, Mount Holly; secretary and treasurer, Dr. Lucius N. Glenn, McAdenville, and censors, Drs. Charles E. Adams, Gastonia; D. A. Garrison, Bessemer City, and John H. Jenkins, Dallas.

Linn County (Iowa) Medical Society.

This society was organized at Cedar Rapids, September 2, with fifty members, under the constitution and by-laws recommended by the American Medical Association, with the following officers: Dr. Ward Woodbridge, Central City, president; Dr. George R. Skinner, Cedar Rapids, vice-president and delegate; Dr. Hollis W. Bender, Cedar Rapids, secretary; Dr. Frank S. Skinner, Marion, treasurer, and Drs. Austin H. Johnson, Cedar Rapids; John Hamilton, Cedar Rapids, and John W. LaGrange, Marion, censors, and Dr. George R. Skinner, Cedar Rapids, delegate to the Iowa State Medical Society.

Portage County (Wis.) Medical Association.

With the aid of Dr. John F. Pritchard, Manitowoc, councilor for the Eighth District, this society was organized at Stevens Point, September 1, with an initial membership of 13. The plan of organization suggested by the American Medical Association was adopted and the following officers and committees elected: Dr. Galen Rood, Stevens Point, president; Dr. Augustus H. Guernsey, Amherst, vice-president; Dr. Carl von Neupert, Jr., Stevens Point, secretary and treasurer; Drs. William F. Atwell, Daniel S. Rice and Carrie A. Frost, all of Stevens Point, censors, and Drs. Frank A. Southwick, Myron G. Rood and John D. Lindores, all of Stevens Point, committee on by-laws.

Societies.

COMING MEETINGS.

Medical Society of the State of Pennsylvania, York, Sept. 22-24.
American Association of Obstetricians and Gynecologists, Chicago, Sept. 22-24.
American Academy of Railway Surgeons, Chicago, Oct. 1-2.
Colorado State Medical Society, Denver, Oct. 6-8.
Medical Association of the District of Columbia, Washington, Oct. 6.
Idaho State Medical Society, Boise, Oct. 8-9.
Mississippi Valley Medical Association, Memphis, Tenn., Oct. 7-9.
Vermont State Medical Society, Bellows Falls, Oct. 15-16.
New York State Medical Association, New York City, Oct. 19-22.

Ohio Valley Medical Association.—This association will hold its annual meeting at Evansville, Ind., November 12 and 13.

American Academy of Railway Surgeons.—The academy will meet at the Great Northern Hotel, Chicago, October 1 and 2, under the presidency of Dr. Luther Sexton, New Orleans. An interesting program is announced.

Nashville Society of Colored Physicians.—At the annual meeting, September 1, Dr. C. O. Halley was elected president; Dr. W. A. Reed, vice-president; Dr. A. M. Townsend, secretary, and Dr. Preston R. Burrus, treasurer.

Ohio Valley Medical Association.—This organization will hold its next annual meeting in Evansville, Ind., Nov. 12 and 13, 1903. The field of its membership has been extended to cover the four states of Ohio, Indiana, Illinois and Kentucky.

Medical Society of the State of Pennsylvania.—Extensive preparations are being made at York for the entertainment of the members of this society, which holds its annual meeting, September 22-24, under the presidency of Dr. William M. Welch, Philadelphia.

Henry County (Ky.) Medical Society.—At the annual meeting held in New Castle, August 26, Dr. C. R. Martin, Sulphur, was elected president; Dr. John C. Cassity, Eminence, vice-president; Dr. John Nuttall, New Castle, secretary, and Dr. Albert P. Dowden, Eminence, treasurer.

Reading (Pa.) Medical Association.—At the annual meeting held August 31, the following officers were elected; President, Dr. John Shartle; vice-president, Dr. Harry F. Rentschler; secretary, Dr. Clara S. Keiser; treasurer, Dr. Oan J. Thompson; censors, Drs. Fremont W. Frankhauser, Israel Cleaver and James W. Keiser, and curator, Dr. S. Banks Taylor.

Morehouse County (La.) Medical Society.—At the annual meeting Dr. Charles D. Clark, Mer Rouge, was elected president; Dr. A. W. Jones, Jones, vice-president, and Dr. Otis M. Patterson, Bastrop, was re-elected secretary and treasurer. The society adopted the new constitution and by-laws of the Louisiana State Medical Society, in order to affiliate with that organization.

West Tennessee Medical, Dental and Pharmaceutical Society.—This society, whose membership is made up from colored physicians, dentists and druggists, was organized at Humboldt, August 26 and 27. The following officers were elected: President, Dr. I. S. Sawyers, Humboldt; vice-presidents, Dr. R. G. Martin, Memphis, and T. L. Anderson, Ph. C., Jackson; secretary, W. D. Holder, D.D.S., Jackson; corresponding secretary, Dr. W. A. Cocolough, and treasurer, Dr. John L. Light, Jackson.

Mississippi Valley Medical Association.—The 1903 meeting of the Mississippi Valley Medical Association will be held at Memphis, Tenn., Oct. 7-9, 1903. An excellent program has been prepared and a large attendance is anticipated. The profession of the lower part of the Mississippi Valley, it is expected, will be largely represented at this meeting, and it is to be hoped that there may be a good attendance from the northern part of the middle west. Memphis is accessible by direct railroad connection with most cities of the middle west.

New Hampshire Surgical Club.—This organization held its eighth annual meeting at North Conway, September 3. Fifty members were present. Dr. Milton S. Woodman, West Lebanon, read a paper on "Carbuncle," which was discussed by Dr. Charles R. Walker. A paper on "Pathology and Surgical Treatment of Bright's Disease" was presented by Dr. Seth Chase Gordon, Portland, Maine. A banquet followed, at which Dr. James I. Greeley, Nashua, acted as toastmaster. The officers elected are: President, Charles R. Walker, Concord; vice-president, Dr. J. Franklin Robinson, Manchester; secretary and treasurer, Dr. Nelson W. McMurphy, Concord; executive committee, Drs. Charles R. Walker, N. W. McMurphy, P. T. Haskell and D. S. Adams.

BUFFALO ACADEMY OF MEDICINE.

Special Meeting, held Sept. 8, 1903.

President, Dr. Joseph W. Grosvenor, in the Chair.

Fourth of July Legislation.

A special meeting was held September 8 in order to have preventive measures adopted by city ordinances to lessen accidents from Fourth of July explosions and from bonfires.

Proposed Ordinances.

DR. LUCIEN HOWE presented a set of ordinances and stated the reasons for their adoption. The ordinances are as follows:

Section 1. The sale of any fireworks containing dynamite or any other explosive more powerful than ordinary black gunpowder to any person without permission from the mayor, or the sale or gift to any child or children without the written consent of the parent, of any gun or pistol, of any kind of toy cannon, or any firecracker or torpedo, rocket, balloon or other forms of fireworks or explosive is hereby prohibited.

Any violation of the provision of this section will subject the offender to arrest and fine of $50 for each offense.

Sec. 2. No person shall fire or explode or send off in any avenue, street or alley in the city of Buffalo, any firecracker or torpedo, rocket, balloon or other forms of fireworks or explosives, nor build bonfires, nor discharge any cannon, gun, pistol or any other firearm, or any gun loaded with a dangerous missile.

Any violation of this section shall subject the offender to arrest and fine of not less than $10 nor more than $25 for each offense. Moreover, the offender, or, if he be a minor, his parents or guardian, shall be held responsible for any injury which may result directly or indirectly to person or property from any such explosives or fires.

The provision of this section shall not apply to the public parks, but it shall apply to the streets or avenues connecting these parks with each other.

Sec. 3. Any person, not an employé of the police department, who shall furnish evidence leading to the conviction of one who has violated either of the two preceding sections of this ordinance, shall be entitled to receive half of the fine imposed.

Accidents in Buffalo.

Dr. Howe stated that there have been 209 recorded accidents from Fourth of July celebration in Buffalo since 1895. Last year 60 were reported and there are doubtless many more accidents which are not reported at all. Boston, Providence,

New York, Philadelphia, Cleveland and St. Paul have all adopted restrictive ordinances. He stated that this ordinance would permit the boys to use the parks only for firing off fireworks, and the use of those places would have to depend on the park board.

SUPERINTENDENT OF POLICE BULL suggested that the ordinance should be so framed as to be enforced. The restrictions should be placed on toy pistols, toy cannons, giant crackers and giant torpedoes. The sale of cartridge pistols to children under 16 years is already prohibited. To make the parent responsible for the use of pistols in the main is imperative, for if the parent can be reached by the police department the regulations can be enforced.

HEALTH COMMISSIONER GREEN stated that there were 459 cases of tetanus in this part of the country as a result of injuries received the last Fourth of July. The toy pistol that discharges a small cartridge does the most harm. If dealers are allowed to sell dangerous fireworks children will get them.

DR. ROSWELL PARK estimated that 8,000 deaths from tetanus as a result of the toy pistol had occurred in this country in the last twenty years.

Co-operative Committee Appointed.

A resolution was passed naming a committee of five to cooperate with different departments of the city government and with various public bodies to bring about the enactment of an ordinance embodying the propositions laid down in the draft presented. Drs. Lucien Howe, Walter D. Greene, Roswell Park, Eugene Smith, and Peter W. Van Peyma were appointed as such committee.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Eczema.

Success in the treatment of eczema, according to G. P. Katzenstein in the *Post Grad.*, depends on the practitioner's ability to observe the various types and stages of the disease. Attention, according to the author, must be directed to the patient's general health, diet, constipation, urine and personal hygiene; when indicated, tonics should be given, such as strychnin, iron, quinin and cod-liver oil.

He recommends the wine of antimony in doses of ten or fifteen minims in the treatment of the acute stages of the highly inflammatory eczemas.

If lithemia is present it must be corrected. Arsenic must not be employed in the acute or subacute eczemas, as it stimulates the nerves of the skin and aggravates the condition. In the chronic dry forms and the recurrent eczema of the hands and feet it is useful, serving as a tonic to the vasomotor system. The use of soap must be avoided, instructing the patient to use cold cream, sweet oil or olive oil in removing dried crusts and exudates.

Itching, which is the prominent subjective symptom, may be allayed by the use of phenol, resorcin, camphor, menthol and oil of cade prescribed in the following combinations:

℞.	Phenol	gr. x-xx	65-1.30
	Hydrarg. chloridi mitis	gr. xx-xl 1.30-2	65
	Pulv. zinci oxidi		
	Pulv. amyli, āā	3ii 8	
	Petrolati	3iv 15	

M. Ft. unguentum. Sig.: Apply locally.

In conjunction with the foregoing ointment the following lotion may be applied locally through the day:

℞.	Resorcin		
	Acidi borici, āā	3i 4	
	Pulv. zinci oxidi	3ii 8	
	Glycerini	3i 4	
	Aquæ q. s. ad	℥iv 120	

M. Sig.: Apply locally during the day.

In the vesicular form of eczema and in eczema rubrum accompanied by exudation the following is serviceable as a cooling ointment:

℞.	Camphoræ	gr. xv 1	
	Phenol	gr. xx 1	30
	Pulv. zinci		
	Kaolin		
	Aquæ		
	Petrolati, āā	3i 4	

M. Sig.: Apply locally.

Where a protective dressing is indicated the following may be applied:

℞.	Glycerini		
	Gelatin, āā	℥iss 45	
	Pulv. zinci oxidi	℥iii 90	
	Aquæ	℥iv 120	

M. Sig.: Heat over a water bath, and while warm apply locally and cover with cotton.

Ointments containing oil of cade, salicylic acid and ichthyol are more useful in the treatment of the chronic papular forms of eczema where stimulation is required.

For the eczemas of children, which occur in the summer, the following lotion is preferable:

℞.	Resorcin		
	Glycerini, āā	3i 4	
	Pulv. zinci oxidi	3ii 8	
	Acidi borici	3i 4	
	Ol. amygdalæ dulc.	℥ii 60	
	Aquæ calcis q. s. ad	℥iv 120	

M. Sig.: Apply locally.

Eczema appearing on the hairy regions of the body can be benefited by applying the following lotion:

℞.	Resorcin		
	Glycerini		
	Acidi borici, āā	3i 4	
	Aquæ q. s. ad	℥vi 180	

M. Sig: Apply locally

In the dry form of eczema, accompanied by itching and induration, the following is recommended by the author:

℞.	Phenol	gr. x	65
	Olei cadini	m. xl 2	65
	Pulv. zinci oxidi		
	Pulv. amyli, āā	3ii 8	
	Petrolati	3iv 15	

M. Ft. unguentum. Sig.: Apply locally.

Turpentine in Pneumonia.

The oil of turpentine, according to an abstract in *Merck's Archives*, has been used by W. Thomas of Rhyl very successfully in the treatment of pneumonia. He regards it as almost a specific in those cases complicating influenza. It must be given early, persistently and in adequate doses. He first gives a good dose of calomel and subsequently the following mixture:

℞.	Olei terebinthinæ	3ii-iv 8.-15	
	Pulv. tragacanthæ comp.	3i 4	
	Spts. ammon. arom.	3ii 8	
	Spts. chloroformi	3ii 8	
	Aquæ q. s. ad	℥viii 240	

M. Sig: One teaspoonful every four hours.

The symptoms are rapidly ameliorated, the furred tongue cleansed and moistened, the appetite improved and the bowels opened. The virtues of the turpentine are supposed to be in its antiseptic properties, its ease of absorption, and its stimulating qualities.

Valerian.

The newer remedial agents, according to S. E. Earp in *Med. and Surg. Monitor*, have proven so satisfactory in the treatment of disease that the practitioner sometimes erroneously expects them to accomplish everything and thus reject the old remedies to the detriment of the patient. He therefore reviews the therapeutic action of valerian, the value of which has been proven. The tincture, in strength of 20 per cent., and the ammoniated tincture are the preparations most frequently used. They may be given in doses ranging from one to two drams, flavored with gaultheria or peppermint. He recom-

mends it in cases of delirium tremens, coughs of reflex origin, hysteria and insomnia. The following combinations are recommended by the author:

℞. Tinct. valerianæ ammon. .....ʒii 60
Tinct. piscidiæ
Elix. simplicis, āā.....ʒi 30
M. Sig.: One dessertspoonful every two to six hours.

In nervous disorders of women the following may be given:

℞. Tinct. valerianæ ammon.
Spts. etheris comp.
Tinct. humuli, āā.....ʒii 60
M. Sig.: Two teaspoonfuls in water every hour or two hours.

If this preparation is not given judiciously, according to the author, toxic effects may arise such as are shown by dizziness, vomiting, hiccough, eructations, diarrhea.

In many hysterical disorders the practitioner prescribes preparations containing chloral, potassium bromid, or opium when a proper knowledge of the pathology of the disease would show their contraindication, and the ammoniated tincture of valerian could be of service.

In insomnia from overwork or from leading a strenuous life it is of value, as well as in those cases of insomnia in patients recovering from la grippe, using this preparation as a substitute for the hypnotics.

The dentist could use it with advantage in those nervous cases brought on from the shock of the operation. In disturbances of the menopause or in nervous headache due to excitement it is a valuable antispasmodic. In the neuroses where the heart's action is accelerated or the respiration quickened or in cases of melancholia and hypochondriasis, valerian is of value. He especially emphasizes the importance of valerian in the nervous diseases of children where opium is too often used in its stead, which enhances the dangers of the child's life and aggravates the disease.

Medicolegal.

Amputation Below Elbow Constitutes "Loss of an Arm."—The Supreme Judicial Court of Massachusetts says, in the case of Garcelon vs. the Commercial Travelers' Eastern Accident Association, that it considers the amputation of an arm a little below the elbow to be the loss of an arm in the common acceptation of those words, and within their meaning as used in a policy which specifies merely the "loss of an arm," without mentioning whether the loss is by amputation below or above the elbow joint.

Showing Employment of Physician to Make Examination.—In the case of the Allen B. Wrisley Company vs. Burke, which was brought by the latter party to recover for personal injuries, in the cross-examination of a physician who testified in behalf of the company as to the condition, physically, of the party suing soon after the injury was received, it was developed that the physician had been employed to make the examination for the purpose of becoming a witness in the case, and had been paid for his services in so doing. The fact that the physician had been engaged and paid to make the examination, and for the purpose of giving testimony in the case, the Supreme Court of Illinois holds, was proper for consideration, as bearing on the weight and value of his testimony. The fact that, in developing the proof that the witness was employed and paid to make the examination, it incidentally appeared he was paid by an accident company, did not constitute error demanding the reversal of the judgment.

No Compulsory Examination in Slander Case.—The Court of Criminal Appeals of Texas says that, in Bowers vs. State, a criminal prosecution for the slandering of a female, where the defense consisted of an effort to prove the truth of the allegation; that is, that the accused had had carnal intercourse with the prosecutrix, a motion was made to have the trial court order an examination of the private parts of the prosecutrix by reputable physicians, alleging that such examination would show that her hymen had been ruptured and destroyed by a male organ penetrating the same. This motion was objected to by the state on the ground that the court had no authority to make such order, and the court sustained the objection, and declined to appoint the committee of physicians, and to authorize them to subject the prosecutrix to a private examination. In refusing to make the order, when the prosecutrix objected to the examination, the Court of Criminal Appeals holds that the court below did not err. Of course, it says, if the prosecutrix had been willing to submit to the examination, and such examination would tend to solve a disputed issue in the case, it would be entirely competent for the court to make the order.

Not Competent to Testify as to Miscarriage.—The Court of Appeals of New York holds, in the personal injury case of Gray vs. the Brooklyn Heights Railroad Company, that lay witnesses, even with some experience in midwifery, should not be permitted to compare germs of life at its earliest stage and announce their conclusions. The subject is not a matter of common knowledge or observation. Here the injured party commenced to bleed after a slight jolt in a street-car collision. Soon after, something about as large as an egg, and colored like blood, passed from her, and after that she bled for about two weeks longer. Whether or not it was a miscarriage was in dispute, and she was permitted to state that it was one. The other women, who claimed to have had miscarriages, were also permitted to state how what she had compared with what passed them. The court holds that these rulings were erroneous. Manifestly, it says, these witnesses could not have expressed the opinion directly that the party suing had had a miscarriage, yet each was permitted to express that opinion indirectly by saying, in substance, that what happened to the party suing was the same as had happened to herself, when she had, in her opinion, a miscarriage. She could not say that this party's case was like her own. A witness may testify that he had a cold, as that is a matter of common knowledge and experience, but he can not say, "I had pneumonia, and the plaintiff's symptoms were like mine," because it is not the statement of a fact within the range of common knowledge and observation, but of two opinions, both of which are incompetent. The witnesses should have stated the facts only, and the jury, guided by the opinions of the physicians so far as they deemed them reliable, should have drawn the conclusion.

Christian Science and the Treatment of Disease.—The Supreme Court of Pennsylvania says, in the matter of the application of the First Church of Christ, Scientist, for a charter under the laws of the state of Pennsylvania, that the application set forth that the purposes for which the corporation was to be formed were to "establish and maintain a place for the support of public worship and to preach the gospel according to the doctrines of Christ Jesus as found in the Bible and the Christian Science text-book, 'Science and Health, with Key to the Scriptures,' by Mary Baker G. Eddy." The Supreme Court is inclined to think that the evidence was not sufficient to support a finding that the corporation itself was to be one for profit. It says that there was proof that the individual healers, who are constituted and sent out by the society, do receive compensation for their services; but this seems to be a personal recompense, with which the society has nothing to do. But the court below, in its supplemental opinion, went beyond this question, and adopted in substance the conclusion of the master that the practice of the art of healing or curing disease in the manner set forth in Mrs. Eddy's book is injurious to the community, because it is opposed to the general policy of the law of Pennsylvania relative to the existence and treatment of disease. It was the duty of the court below to refuse the charter, if, in the exercise of sound legal discretion, he found its purpose, in whole or part, included anything injurious to the community. Can it be said that there was an abuse of discretion in the finding in this case? We are not to consider the matter from either a theological or metaphysical standpoint, but only in its practical aspects. It is not a question as to how far prayer for the recovery of the sick may be efficacious. The common faith

of mankind relies, not only on prayer, but on the use of means which knowledge and experience have shown to be efficient; and when the results of this knowledge and experience have been crystallized into legislative enactments, declarative of what the good of the community requires in the treatment of disease, and of the qualifications of those who publicly deal with disease, anything in opposition thereto may fairly be taken as injurious to the community. Our laws recognize disease as a grim reality, to be met and grappled with as such. To secure the safety and protect the health of the public from the acts of incompetent persons the law prescribes the qualifications of those who shall be allowed to attempt the cure or healing of disease. It is not for the purpose of compelling the use of any particular remedies, or of any remedies at all. It is only designed to secure competent service for those who desire to obtain medical attendance. In certain diseases the individual affected may be the only one to suffer for lack of proper attention; but in other types, of a contagious or infectious nature, they may be such as to endanger the whole community. And here it is the policy of the law to assume control and require the use of the most effective known means to overcome and stamp out disease, which otherwise would become epidemic. In such cases, failure to treat, or an attempt to treat by those not possessing the lawful qualifications, are equally violative of the policy of the law. It may be said that the wisdom or the folly of depending on the power of inaudible prayer alone, in the cure of disease, is for the parties who invoke such a remedy. But this is not wholly true; "for none of us liveth to himself, and no man dieth to himself," and the consequence of leaving disease to run unchecked in the community is so serious that sound public policy forbids it. Neither the law, nor reason, has any objection to the offering of prayer for the recovery of the sick. But in many cases both law and common sense require the use of other means which have been given to us for the healing of sickness and the cure of disease. There is ample room for the office of prayer, in seeking for the blessing of restored health, even when we have faithfully and conscientiously used all the means known to the science and art of medicine. The findings of fact by the learned master, and his conclusions of law therefrom, and the opinion of the court below, in which they are summarized and approved, vindicate the action taken. Under the well-defined policy of the law of Pennsylvania, as at present existing, we are satisfied that there was no abuse of sound legal discretion in refusing the application for a charter. The appeal is quashed, and the order refusing to approve the charter is affirmed.

1 *The Adams-Stokes Syndrome, with Report of a Case. Peter Bassoe.
2 *The Prognosis and Orthopedic Treatment of Acute Anterior Poliomyelitis. (To be concluded.) Walter G. Stern.
3 *Listerism; Its Past, Present and Future. G. S. Towne.
4 *The Operative Treatment of Tuberculous Glands of the Neck. J. G. Sheldon.
5 *Regicides; Sane and Insane. (Concluded.) E. C. Spitzka.
6 *Hay Fever: A Cause and a Cure. Frank E. Stowell.
7 Celluloid as a Material for Flat-foot Plates. Harold W. Jones.
8 A Case of Atropin Poisoning. C. B. Cortright.

1. **Adams-Stokes Syndrome.**—The points especially emphasized by Bassoe are summarized by him as follows:

1. The Adams-Stokes symptom-complex is not a clinical entity. It may supervene in various diseases involving the heart, vagus nerves, or medulla oblongata.
2. It is particularly likely to set in when the upper part of the ventricular septum is diseased.
3. Arteriosclerosis is not essential for its production.
4. Its occurrence in a well-studied case of localized lesion of the intramedullary portion of the accessorius nerve supports the hypothesis that the inhibitory fibers of the heart are derived from this nerve.
5. A lesion of the ventricular septum is capable of producing bilateral degeneration of the extramedullary cardiac fibers of the vagus nerves.
6. The existence of bradycardia in a case with bilateral vagus degeneration proves the muscular origin of bradycardia in such a case as the inhibitory influence of the vagi then must be absent.
7. The bradycardia is the fundamental feature of the Adams-Stokes syndrome. The nervous symptoms vary largely, according to the susceptibility of the nervous centers to the circulatory disturbance induced by the bradycardia.

2. **Poliomyelitis.**—Stern's article will be reviewed when concluded.

3. **Listerism.**—Towne gives a résumé of the history of aseptic and antiseptic surgery, showing that the scientific basis of Lister's method has never been successfully attacked, and that the decrease of mortality since its use has placed surgery almost at the head of the modern sciences.

4. **Tubercular Glands of the Neck.**—Sheldon's article is largely an anatomic one showing the conditions to be met in operating for tubercular glands. He thinks that the successful and complete removal is a necessity; partial operations in his practice have been followed by relapses. He reports three cases of death following operations for tuberculous glands of the right side of the neck, and considers them possibly due to the introduction of post-operative debris into the right lymphatic duct. Consequently, he no longer disregards this vessel, but clamps and ligatures the base of the mass of tissue removed from the subclavian triangle in his operations. For details the paper itself should be referred to.

5. **Regicides.**—Spitzka argues that we are not to consider the regicide as necessarily degenerate or insane. He points out that in many, if not in most cases, they have had rational incitation to their act, and their surroundings and associates have been such as to encourage it.

6. **Hay Fever.**—The theory of hay fever held by Stowell is that it is a nervous trouble not due to nasal irritation, but more especially to the actinic solar rays. He has, therefore, utilized smoked glasses for the early form of hay fever in his own case, and finds decided relief from their use. In one or two other persons there were somewhat similar results. He would be glad to have further trials of this method.

9 *Acute Bulbar Paralysis Due to Hemorrhage and Softening of the Pons and Medulla; with Report of Cases and Autopsies. Charles L. Dana.
10 Abscess of the Left Temporosphenoidal Lobe of Otitic Origin; Operation; Recovery. E. Gruening.
11 *The Rational Treatment for Mouth Breathing. W. H. Fitzgerald.
12 *The Internal Administration of Methylene Blue as an Aid in the Diagnosis of Urethroperineal Fistula. Richard Lightburn Sutton.
13 A Possible Case of Infant Poisoning as a Result of Abnormal Mental and Physical Condition in the Mother. Chester J. Stedman.
14 A Case of Smallpox in the Fetus. J. H. Franklin.

9. **Bulbar and Pontine Paralysis and Softening.**—Dana's article is a very elaborate one, giving the anatomy, etiology, pathology, clinical symptoms, etc., of the conditions of hemorrhage and softening of the pons and medulla causing acute bulbar paralysis. He concludes with rather elaborate reports of personal observations of cases and a bibliography.

11. **Mouth Breathing.**—The method suggested by Fitzgerald for the treatment of mouth breathing is, first, to restore the nose as nearly to the normal conditions as possible, and then insist on the patient using it. He says so long as local applications, sprays, douches and solution treatment are relied on we shall fail. What the nose wants is air and not water or sprays. He treats these cases by regular exercise, using the mouth guard at night for a few weeks. The form of guard he has found best is a small strip of adhesive plaster worn vertically across the center of the mouth. He thinks treatment should be commenced in early infancy. Normal breathing will help to bring about normal development. Without it such development can not be obtained.

12. **Methylene Blue in Diagnosis.**—Sutton reports a case in which methylene blue given by the mouth was effective in diagnosis of the urethral connection of a perineal abscess which could not otherwise be detected. He thinks the method is to be recommended in such cases where the canal is too tortuous for probing or where the genito-urinary tract is sus-

pected, on account of its simplicity, reliability and freedom from pain.

Boston Medical and Surgical Journal.

15 *The Resistance of Tissues as a Factor in the Manual Reduction of Congenital Hip Dislocation. E. H. Bradford.
16 *Privileged Medical Communications. David W. Cheever.
17 *The Workings of the New York Law. Walter Soren.
18 *Privileged Communications to Physicians. Frederick J. Stimson.

15. Congenital Hip Dislocation.—Bradford holds from his study of the subject that the resistance offered by the capsule in congenital hip dislocation is not more important than that offered by the muscles. The chief resistance to forcible abduction is from the strong tendon of the adductor magnus. The resistance to pulling down the head comes from the hamstring group and the long tendon of the adductor magnus and ilio-tibial band. These resistances may be overcome by small incisions at a distance from the hip. In the lighter cases manual manipulation is sufficient. In resistant cases mechanical force, which pulls on and abducts the limb, arranged so as to also directly act on the capsule, is of assistance. Where the tendon of the adductor magnus is so strong that excessive force is needed in stretching, it seems to him advisable to divide the chief resisting tissues rather than to incur the danger of severely bruising the tissues by the force used. Division of the tendon can be done either before the operation of forcible correction or at the same time.

16. Privileged Communications.—Cheever rather advocates the New York law or some modification of it. He suggests that it should be considered unprofessional for the physician to divulge anything confided to him by his patients unless the patients consent or it is a case of crime. In all other cases the confidences should be considered privileged communications, and if a physician declines he should be protected. If he consents to testify he should go before the judge in private.

17. Privileged Communications.—Soren describes the New York law and the amendments that have been made. The obvious lesson to be drawn from its working, he says, is that any new legislation on the subject of privileged communications would have to be contained in eight or nine separate sections in order to take advantage of the points that have made the amendments to the New York law advisable. It would also be well to avoid, if possible, language giving the court such entire freedom of construction. The question in regard to a medical privilege law would be whether more injustice would be caused by it than would otherwise be the case. The fact, however, that they are still amending the New York law stands something in its favor.

18. Privileged Communications.—Stimson maintains that the common law practice is really the best. He sees no reason why a physician's privilege should be used to protect a crime. In instances of actions for damages for personal injury by the patients he sees no reason why the latter should necessarily be protected. If the injury is trivial and the person injured is trying to get up a fraudulent claim, there does not seem to be much injustice in making him confide in the physician at his own risk. In will cases there certainly should be no privilege, he thinks, and it is well known that the New York statute works an injustice on life insurance companies in its present arrangement. In suits between the physician and patient it is not in the interest of the physician, at least, to have the privilege maintained. There is a great class of cases, likely more and more to get into the courts, in matters of marriage, divorce or sometimes wills, where the physical condition and the just or temperate life of some person is concerned. No statute, he thinks, can be drawn which can be safely applied to all these cases, and the absolute exclusion of the physician's testimony would be unwise. It is, therefore, better, he says, to leave the matter to the common law as done at present in Massachusetts and some other states.

24 Mastoid Disease and Meningitis. Seymour Oppenheimer.

19. Infant Mortality.—The following is the summary offered by Freeman of his discussion of infant mortality and its reduction in New York City:

1. The infant mortality of all countries is shockingly high, and this is shown to be unnecessary by the fact that infants that are well cared for show a very low mortality.

2. The influences that contribute to the high mortality are defective feeding, the active cause, and heat and humidity and bad surroundings as contributory causes.

3. There has been a marked decline in infant mortality during the last ten years in the United States, and especially in New York City, due, for the most part, to the decline in mortality from summer diarrhea.

4. This striking decline in infant mortality is due to many agencies. The general adoption of pasteurization and sterilization of milk for infant feeding is by far the most important of these and applies to New York City and the whole of the United States. Other agencies in New York City are the improved city administration, the milk inspection of the department of health, the Straus Milk Charity, the fresh air work of St. John's Guild and similar charities, cleaner streets and asphalt pavements, the new small parks, playgrounds and recreation piers, the improved tenements and the use of diphtheria antitoxin.

20. Respiratory Diseases.—Bergey calls attention to certain evils and neglected prophylactic measures, especially in industrial pursuits where exposure to dust is required. We should give more attention to the value of pure air, and secure for this class of workingmen shorter working hours and less exposure, encouraging them to more outdoor exercise. The condition of city streets is another matter of importance, and undoubtedly favors the general dissemination of specific microorganisms and also lowers the vitality of the respiratory mucosa. He hopes that we will have more efficient street cleaning and transportation lines placed either underneath or above the streets, and the employment of draft horses substituted by other means. The second point to which he calls attention is the deficiency of ventilation in the public schools and their overcrowded condition.

30 *On the Toxicity of Methyl Alcohol in Extracts and Medicines. R. H. Main.
31 Historic Notes on the Laws Governing Civil Malpractice in the Ancient Times and the Middle Ages. Charles G. Cumston.

25. Uncinariasis in Porto Rico.—According to Ashford and King the most favorable conditions exist in Porto Rico for the growth and spread of uncinariasis, uncommonly fine climate, water-soaked soil, perfect culture media, topography favorable to the spread of larvæ, dense shade, density of population, agricultural pursuits, bad sanitation and habits. The authors lay much stress on the importance of eosinophilia as a diagnostic and prognostic point. The disorder is at some period of its course marked by this condition. High eosinophilia is to be looked for in recent cases where the blood regeneration is still active. In chronic cases, where the anemia is profound, it is apt to be low, and to rise after treatment, if the prognosis is good. A fall in the number of eosinophiles, however, is a bad symptom. They notice the symptoms at length and consider the course of the disease, when uninterfered with, to be progressively downward.

26. Epilepsy.—Wherry holds that the convulsion in epilepsy is a salutary process and that without it the condition would be much more serious. It is a conservator of life, he says, standing between alarming autointoxication and possible

death, and points the way in which the epileptic can secure relief. He does not attempt to stop the convulsions, and the use of bromids, he thinks, for this purpose is a mistake.

27. **Ear Massage.**—Amberg holds that massage and ear inflation are overdone, and insists on the importance of the use of Siegle's pneumatic ear speculum for diagnostic purposes. The treatment should be continuously controlled by hearing tests, and any local treatment, if injurious, naturally should be absolutely prohibited.

29. **Coffee.**—The antiseptic qualities of coffee are noticed by Crane and Friedlander, who have experimented on its bacteriocidal properties. They find that roasted coffee is a decidedly active agent in the destruction of germs, including some of the more serious and important ones. Just how it acts they do not venture to say. They find it can not be due to caffein, as that had very little effect in retarding putrefaction, and tea infusions have not this property. There is no reason to suppose that the oil abstracted by Erdman and Bernheimer has any such effect, and caffetannic acid is abundant in green coffee, which is not effective. The suggestion is made that the antiseptic qualities may be partially due to an aldehyd, but the final solution of the question must wait for a more definite knowledge of the changes induced by roasting the substance.

30. **Methyl Alcohol.**—This is, in substance, the same article as that noticed in THE JOURNAL of September 12, ¶52, p. 686.

36. **Dysentery Bacillus.**—The conclusions reached by Gay are that the dysentery bacilli (Shiga) fall into two types according to their cultural and agglutinative reactions. These, however, are not absolute, but relative; they serve to indicate a closely related group of organisms. The bacteriolytic differences serve to distinguish the two types of dysentery bacilli. The relative value of these distinctions is emphasized by the protective power of antidysenteric serum, which is effective, in different doses, for both types of the micro-organism. Human complement is capable of activating antidysenteric serum from the horse. Passive immunity to the dysentery bacillus is of brief, active immunity, of much longer duration in the guinea-pig. The dysentery bacillus vaccines increase in toxicity for a time, at least, and the increase is associated with disintegrative changes in the bacilli.

37. **Dysentery Bacillus.**—Gay and Duval describe cases which seem to have been caused by this organism, which has the characteristics of a group of organisms rather than one single, well-defined species. They think, however, the distinction of the types into the dysentery and pseudodysentery bacillus, as attempted by Kruse, Martini and Lentz, is artificial and unwarranted with our present knowledge.

46 *Dispensaries for Tuberculosis, with a Description of the Tuberculosis Department of the Boston Dispensary. Edward O. Otis.
47 *Home and Sanatorium Treatment of Tuberculosis. William Porter.
48 *The Importance of the Nerve Centers in Pulmonary Consumption. Thomas J. Mays.

46. **Dispensaries for Tuberculosis.**—The advantages of these institutions and the order of work of the Boston Dispensary are described by Otis. The objects of a tuberculosis dispensary, according to his views, are: Complete investigation of the patient, personally, and his surroundings; the instruction both of the patient and his household in the hygiene of tuberculosis; the free supply to poor patients of pocket and house spittoons; securing entrance into sanatoriums for curable cases and into consumptive hospitals for incurable ones if they can not be properly cared for at their homes, and if neither of these can be secured, the treating of them as well as possible at their homes; aiding poor patients to obtain suitable food and other necessary articles; affording an opportunity to physicians to send their poor patients for diagnosis when desired, as well as advice and assistance in treatment. Lastly, he mentions the opportunity for scientific study and investigation and for clinical instruction of physicians and students in regard to this condition. The equipment should be a suitable waiting room; a receiving or consulting room where histories are taken, together with pulse, temperature, respiration and weight; several small examining rooms, a small laboratory for sputum examination, etc.; a dark room for laryngoscopic work, and possibly an *x*-ray room. The rooms should all be well ventilated and periodically disinfected. There should be a staff of four chief physicians, each serving three months, with plenty of assistants.

47. **The Home and Sanatorium Treatment of Tuberculosis.**—Porter describes the proper methods of care for patients at home and in the sanatorium, the education of the public, necessity of proper ventilation, rest, exercise, etc., instruction as to clothing, hydrotherapy, dietetic treatment, etc. He remarks that the results of what has already been done, especially in Germany and in some sanatoriums of this country, are most encouraging.

48. **Nerve Centers in Consumption.**—Mays claims that the respiratory organs are biologically the most immature and most predisposed to diseases of all the viscera, and that degeneration or imperfection of the vagi or their nuclei aids this tendency. He remarks in support of his views that pulmonary consumption is much more frequent among the insane and mentally defective than in other persons, and that the increase of insanity among the negroes since the strain on their nervous system following the abolition of slavery is also an evidence of their correctness.

49 *The Treatment of Hyperacidity of the Stomach Contents, with Special Reference to the Carbohydrate or Meat-free Diet. David Murray Cowie.
50 *Fibromata as Complications of Pregnancy. Reuben Peterson.
51 A Daily Study of Foods, Producing or Not Producing Casts, Fatty Epithelia and Albumin in Urine. (Continued.) Ephraim Cutter.

49. **Hyperchlorhydria.**—The advantages of a carbohydrate diet are noted by Cowie, who points out the stimulating action of a more proteid diet on the stomach secretion. He would add to it a certain amount of fats, and especially the use of milk between meals. The medical treatment is limited solely to the use of alkalies, though belladonna and opium have been advocated to reduce the activity of the glands. Stomach washings should be dispensed with as a rule in cases of normal or hypermotility. It is well to reduce the number of lavages as much as possible, though where there are signs of retention or atony lavage should be carried out systematically. Too much alkali in solution should be avoided and only be used when the stomach has been found to be acid. His practice does not give the theoretical results to be expected from diastase preparations. Attention to mastication and the use of dry foods will thoroughly obviate the necessity for these

substances. Constipation should be looked after and peptic ulcer be considered before instituting too radical measures.

50. **Fibromata.**—The dangers of these growths in pregnancy are treated by Peterson, who considers pressure symptoms a more important indication for interference than the size or position of the fibromata. The number, size and position will determine the exact nature of the operation. First, the abdomen is opened, and if there is a single growth and it can be removed easily, myomectomy may be performed and labor allowed to continue by the natural channels. This will be exceptional, however. Usually the choice would be between a cesarean section and supervaginal or panhysterectomy.

55 Gunshot Wound of Abdomen, with Fourteen Perforations of the Intestine; Operation; Recovery. Wilbur O. Jenkins.
56 A Case of Intestinal Perforation from Gunshot; Operation; Recovery. M. G. Moore.

52. **Intestinal Spasm.**—Pantzer reports four cases of spasmodic constriction of the intestines, 3 of them associated with gallstones and 1 with a suspicion of syphilis. In 1 case there was a perforation of the combined walls of the gall bladder and colon with a stone 5⅛ inches in diameter presenting at the opening. The perforation was closed, the gall bladder emptied of several gallstones and complete relief obtained. The other 2 gallstone cases ended fatally. He discusses the subject generally and the literature to some extent.

54. **Tetanus.**—The rational treatment of tetanus here advocated consists in venesection followed by the injection of normal saline solution. McOscar refers to a case reported previously thus treated, though antitetanic serum was also employed. The result was recovery, though the case was an acute one. He thinks that bleeding and subsequent flushing with normal salt solution had much to do with the good results. The treatment for tetanus, he says, should be first prophylactic by early and free incision and thorough cleansing of every suspicious wound. If the culture shows the tetanus bacillus a liberal immunizing quantity of antitetanic serum should be administered subdurally without waiting for symptoms. When the disease has declared itself the patient should be bled as freely as his condition will admit, followed by generous intravenous injections of normal saline, repeated at sufficient intervals, which will be determined by the rapidity of elimination of the kidneys. After the abstraction of blood the antitetanic serum should be administered in large doses hypodemically.

71 A Mastoid and Auricle Retractor. Frederick L. Jack.

57. **Atrophic Rhinitis.**—Freudenthal considers that ozena is an atrophy of the nasal interior conditioned by atmospheric influences—xerasia. The bones of the turbinated bodies appear to be early affected, and the effects of lack of humidity in the air are apparent in all parts. To convert this atrophy into ozena the invasion of a bacillus similar to Friedländer's pneumobacillus is necessary. This usually occurs at an early period of life, perhaps caused in some cases by direct transmission from the vulva. Accessory sinus disease often appears as secondary to the ozena. After all that has been said ozena is to be considered as a genuine and autochthonous disease, resulting from atrophy of the nasal interior.

72 *Some Observations on the Use of Roentgen Rays in Dermatology. Henry W. Stelwagon.
73 *The Rationale and the Indications for the Therapeutic Use of Roentgen Rays. William A. Pusey.
74 *The Roentgen Rays in Dermatology. Edward B. Bronson.

72. **The Roentgen Rays.**—Stelwagon discusses the values of the coil and static machine as a source of Roentgen rays. He prefers the coil if the electric current is handy or the recharging of the storage battery is feasible. It is more steady and works better in all kinds of weather. For other purposes besides *x*-ray work or where electric currents or the recharging of batteries is not feasible, the static machine should be preferred. A coil with a capacity of a six-inch spark and a static machine giving a good eight-inch spark, will do excellent work. The vacuum is another factor. He says that a moderately low vacuum, equal to a spark gap of about 2 inches, has been what he has used and has seemed to him satisfactory. For protectors he has devised a wooden screen fifteen inches in diameter, one side covered with lead foil and arranged with a head rest, acting both as a protecting screen and a tube holder. When the distance of the tube from the patient is more than five or six inches, a funnel can be attached to the screen with rubber bands and the projecting aperture brought directly over the part to be treated. For the protection of the hands, which is important, he has come to use double mittens, one much larger than the other, the smaller pair enveloped in tin foil, which can be renewed from time to time. The scalp may require attention and protection, and he has noticed that some of his patients have complained of slight dizziness or headache, and he thinks he has suffered so himself. He does not use the *x*-ray treatment for everything, and except in epithelioma, lupus vulgaris, cutaneous tuberculosis, lupus erythematosus, etc., he has employed it only where the cases have proven rebellious to the ordinary methods. The most favorable cases in his experience are those of rodent ulcer occurring in the neighborhood of the eyes. He does not believe in pushing the treatment to actual destructive action, but he thinks that few cases will show much progress unless the *x*-ray affects to a degree of producing a slight flush; usually an extremely slight *x*-ray erythema. He always begins with the tube about 10 or 12 inches with an exposure of five minutes, and gives the treatment, as a rule, twice weekly for two weeks. Then, if no reaction occurs, he speaks of prolonging it fifteen or twenty minutes. A moderate grade of dermatitis may be excited, causing a discontinuance. He has employed the *x*-ray treatment in acne, besides the diseases mentioned, and found it useful. In eczema his moderate experience has led him to think something of its value. In keratosis of the palms and soles he thinks it promises much, and he has had it produce a disappearance of the eruption in psoriasis. Local hyperidrosis is another condition in which he has found it of value. He considers it of first importance in epithelioma, and that it has a wide range otherwise. In eczema, psoriasis and other inoffensive dermatoses he would reserve it for cases that prove intractable to treatment otherwise.

73. **The X-Ray.**—Pusey describes the action of the *x*-ray on the skin as it has been determined. He believes that it acts primarily on the tissue cells, later on the blood vessels. The key to the explanation of the use of the *x*-rays in malignant disease is that it has a quicker action on pathologic tissues than on normal ones. He reviews the various disorders in which he found it of value, including hypertrichosis, sycosis,

comedo, acne, rosacea, hyperidrosis, as well as eczema, lupus, lichen planus, psoriasis and other disorders where the absorption of inflammatory products is desired. His experience with eczema has been favorable as in the case of other workers. The anodyne effects of the *x*-rays are also of value, especially in itching troubles. In favus and tinea tonsurans he has not established its permanent value. It is possible that it might be of use in causing exfoliation of the nail substance, and where it is desired to cause atrophy or decrease in the functional activity of the sebaceous glands.

74. **X-Ray Burns.**—Bronson remarks that while our knowledge of what produces the effect is vague, there is no obvious reason why there should not be a large margin of individual susceptibility. Low tubes seem to be more dangerous in this respect than the high tubes, which are presumed to be more penetrating and suitable for deeply-seated troubles. He discusses the distance of exposure and mode of application. He thinks the standard is 10 minutes at eight inches for the first exposure. He gradually increases this later. No measure, he thinks, requires greater circumspection in its employment or a nicer adjustment of details.

77. **Gallstone Disease.**—Mayo remarks on the success of gallbladder surgery. In 582 operations he has had but 17, or 3 per cent., that required a secondary operation. It is possible, however, that others may have operated on some of his cases, so this figure is not absolute. Experience has taught him how to get over the defects of his earlier work and avoid the causes which lead to subsequent troubles. He remarks in this connection that a few patients who have had cholecystostomy performed will have a colic or two and transient jaundice within the first month or two after the operation, but usually these do not recur. They are probably due to the non-emptying of the crippled gall bladder with sufficient promptness. Unless there is more than a single spell of pain after closure of the fistula a secondary operation may not be required. The most common cause of secondary symptoms is incomplete removal of stones. This, however, is avoidable with sufficient care. Stones in the cystic duct may escape attention, hence the importance of great care in its exploration. In such cases if the stone completely obstructs the duct he clamps it below the obstruction and cuts it off and then performs cholecystectomy from below upward. It may be done almost without cutting by simple traction. It is important to explore the ducts with the fingers before opening the gall bladder in every case, as stones are sometimes overlooked in the common duct where they may lie quiescent for years. One cause of failure from cholecystostomy is from secondary obstruction of the cystic duct, possibly eventuating in a mucous fistula or repeated attacks of colic, hence the advisability of generally excising the gall bladder whenever the cystic duct is involved. In this way he has in his later practice eliminated this most common cause of secondary trouble. In septic cases long-continued drainage is necessary; severe symptoms may follow too early closing of the fistula. Cancer may be said to be secondary to stone formation, and may occur after operation or, if present, be mistaken for inflammatory conditions. All thick-walled gall bladders should be looked on with suspicion. As they are functionally useless cholecystectomy is better than cholecystostomy. Chronic pancreatitis may exist at the time of operation and require long-continued drainage. The condition of the pancreas should be observed at the same time as that of the ducts. If disease is present there is the choice of cholecystenterostomy with the Murphy button in addition to removing the stone, or of draining for a long time. In the one uncomplicated case in his experience which required a secondary operation, the gall bladder was very large and the fistula did not close. On dissecting out the gall bladder it was found that, by low attachment to the abdominal incision it had formed a channel in which in certain positions of the body bile would gravitate outward. After cholecystostomy the gall bladder should be attached as high up in the incision as convenient. Persistent biliary fistula usually means obstruction of the common duct. He holds that every one understands the importance of not attaching the gall bladder to the skin. In earlier days persistent biliary fistula was usually due to the mucocutaneous suture, the evils of which he does not need to point out. The turning in of the margins of the incision in the gall bladder and the tying of a purse-string suture closely about the drainage tube, as in Kader's gastrostomy, hastens the healing of the fistula. Two possible or rather common causes of failure to effect a perfect cure that can not always be avoided are post-operative adhesions. Those to the stomach and duodenum are the most common, and may require secondary separation with the use of Cargile's membrane; and hernia, which is not usually troublesome. It may follow a long incision in obese people. While the adhesions usually relieve themselves by stretching, he does not allow the gauze drains to come in contact with the stomach and duodenum on account of their possible development, but interposes a piece of rubber tissue and leaves it from six to eight days until the adherent films surrounding the drains become organized. To avoid hernia, he makes a secondary opening outside the working incision in cases where it is at all likely to occur, close to the ribs, and through this the drainage matter may be brought out. This enables us to carefully close the full length of the original incision. The necessity of this is increased if the opening has been extended downward to remove the appendix.

83 *The Toilet of the Peritoneum in Appendicitis. Stephen H. Weeks.
84 *Toilet of the Peritoneum in Gunshot Wounds of the Stomach and Intestines. George Tully Vaughan.
85 *Simultaneous Catheterization of Both Ureters. Its Advantages. Technic with New Instrument. S. L. Elsner.
86 *Remarks on Cesarean Section for Placenta Previa, with Special Reference to the Life of the Child. Francis D. Donoghue.

83. **Appendicitis.**—No one method is suitable in all cases, Weeks remarks. If there is no pus formed drainage is not required. If a circumscribed abscess exists care should be taken not to infect the general peritoneal cavity by forcible irrigation which may extend the infection. The pus cavities should be cleansed with gauze pads wet with sterile salt solution or sometimes with peroxid of hydrogen diluted with equal parts of sterile water. In such cases the appendix can generally be found and should be removed, and the wound and abscess cavity should be packed with sterile gauze. Where the wall of the abscess is firmly adherent to the anterior abdominal wall and can be opened without opening into the non-infected abdominal cavity, the point of adhesion should be carefully determined and the abscess opened at this point. Concretions should be looked for, as they may lead to sinuses, the abscess cavity evacuated and cleansed with gauze pads or irrigation and the whole cavity packed with gauze. Great care should be used not to break down the abscess wall at any point. Where there is no protecting wall of adhesions and the products of a septic peritonitis have flooded the abdominal and pelvic cavities, thorough irrigation is required, perhaps several times repeated, and drainage.

84. **Gunshot Wounds.**—Vaughan classifies gunshot wounds into two classes—with or without peritonitis. In the first class, if there is no extravasation of the visceral contents, neither irrigation or drainage is required, but if there is extravasation of the visceral contents, thorough cleansing of the peritoneal cavity is necessary and, unless the operator is satisfied that the cleansing is perfect, drainage should be used from the most dependent part—in the female in the vagina and in the male perhaps by tapping the rectovesical peritoneal pouch by an opening into the perineum between the rectum

and the urethra. When the wounds are few, extravasation limited and operation performed early, cleansing by sponging and local drainage may be all that is required. After severe hemorrhage with the formation of blood clots or if there has been imperfect hemostasis, irrigation is indicated as the bloody fluid would form too good a culture medium for germs. In case of local peritonitis the parts involved should be drained, but irrigation should be used with caution to avoid infection of other parts. Generally it is advisable to simply provide drainage. In general peritonitis there is little to be done, but the patient should be given the chance of life by thorough irrigation and efficient drainage in the manner described.

85. **Catheterization of Both Ureters.**—Elsner describes the technic with an especial cystoscope devised by him for double catheterization, which is illustrated and its uses reviewed.

86. **Cesarean Section for Placenta Previa.**—From a thorough study of the subject Donoghue concludes that the conservative Sänger cesarean section should be performed in the case of complete previa, of previa in the primipara, or in the presence of severe hemorrhage or rigid os, when there is a history of previous operative delivery, and it should be considered in all cases where version is indicated, if a reasonably skilled surgeon is available and only an ordinary obstetrician. All these indications are based on a probable viable child, 28 weeks of gestation and upwards. The operation should be performed through the left rectus muscle. Incision of the uterus is not usually followed by hemorrhage, even when the broad ligaments are not constricted. Time should be allowed for contraction and retraction of the uterine fibers before attempting to remove the placenta. If severe hemorrhage has preceded operation the abdomen can be filled with saline solution before it is closed. The shock of such an operation is not greater than that of version or forceps in a woman already exhausted, and within a few minutes the indications to empty the uterus and control the hemorrhage will have been fulfilled.

93 *Treatment of Club Foot in Children Under Three Years Old. A. R. Shands.
94 *The Action of the Uterus During Labor. Elmer Sothoron.
95 *The Kidney in Pregnancy. Robert W. Stewart.

87. **Antenatal Rigor Mortis.**—Two cases are reported by Paddock and others referred to in the literature. He supports the probability of rigor mortis occurring in the fetus by the animal experiments of Tissot, showing conclusively that such a condition does exist. From a medicolegal standpoint it must be admitted that it can occur before birth as well as after. The existence of a new-born dead infant in rigor mortis is not a necessary proof of a life apart from the mother, but it does prove that the fetus was alive shortly before or during birth. The condition often complicates delivery by interference with its normal mechanism.

88. **Peritoneal Adhesions.**—Reed gives quite a full review of the literature of peritoneal adhesions. He says they are responsible for many cases of so-called hysteria and frequently for menstrual pain and irregularity. They produce many abortions, and a certain number of placental and fetal anomalies, sterility and tubal pregnancy may result. Pregnancy and labor are sometimes rendered pathologic by the presence of these adhesions. Many adhesions are undoubtedly destroyed by the growth of the uterus in pregnancy, but their rupture may be attended with fatal hemorrhage. Adhesions between the movable organs of the abdomen and the functionating uterus are only a rare source of danger or a cause of death. Where they are protecting the peritoneal cavity from pus pockets, they are extremely dangerous. The pus should be evacuated as soon as possible after the diagnosis, without reference to the pregnancy, and even if abortion should follow the condition is less serious than when rupture occurs during pregnancy and labor. If the diagnosis is made during labor, it is allowable to temporize until the termination of the case, accelerating the labor if possible by artificial assistance. If the intestines are seriously involved or excluded, the phenomenon occurs in most cases between the fourth and seventh month of pregnancy. When ileus occurs during pregnancy and labor the prognosis is very grave for both the mother and child, especially the latter. The treatment should be surgical.

90. **Electrothermic Hemostasis.**—Goldspohn disagrees with Downes in certain points as regards the electrothermic angiotribe. A large platinum knife is not always sufficiently heated by the current and the time required to oil the blade, apply the forceps, insulate the blade, connect the cable, and then wait for one and a quarter to two minutes for a sufficient effect, is not always less than is required to ligate the parts. He thinks the effort to make this method of hemostasis supersede or displace ligation is not entirely judicious because the heating blade would sometimes have to be located where its insulation would be difficult and insecure. He also thinks that Dr. Downes assumes too much when he holds that the forceps make a permanent closure of such organs as the fallopian tubes or that septic tubes treated by it are also sterilized. The advantages are the greater comfort of the patient after the operation from insensitiveness of the nerves, the probable sterility of the pedicles, the less loss of blood and the avoidance of introducing any foreign body such as ligatures and so on, and the more ideal asepsis in this respect. In vaginal hysterectomy it is superior, also in cancer cases because it more nearly destroys the tissues which compose the stumps or pedicles and thus diminishes the chance of recurrence. It is also of distinct advantage because it does away with the difficult and tiresome method of ligation and the very objectionable use of the clamp, and thereby facilitates an important part of the operation, i. e., the closure of the peritoneal cavity. By avoiding ligatures it prevents secondary hemorrhage and also of infection from such ligatures in their becoming infected before they are absorbed or cast off.

91. **Congenital Dilatation of the Gall Bladder.**—Miller reports and illustrates an interesting case in a child two and one-half years old and reviews the literature of the subject. He thinks it unquestionable that the cyst was a tremendous dilatation of the gall bladder and bile ducts beginning at an early period of intrauterine life; that the common duct was partially obstructed, probably at first by a catarrhal inflammation or calculus and later by the dragging down of the heavy cyst, and that the deformity of the liver was produced by the pressure of the tumor interfering in its development and by atrophy of the liver cells. The case was treated by draining the cyst, hoping that the dilated gall bladder and ducts, being relieved of their contents, would contract and the bile pass along its natural route. If the gall bladder had contracted to a small size and the fistula remained open, and the child suffered from absence of bile in the intestine, his intention was to do a cholecystenterostomy. He has not yet done this on account of certain difficulties, but is keeping in touch with the patient, and it can be done if required.

92. **Round Ligament Tumors.**—Two cases are reported and the frequency, etiology, pathologic anatomy, symptoms, diagnosis and treatment are discussed by Lewis. He thinks these tumors are comparatively rare or are certainly not often reported. There is comparatively little in the literature on the subject. The diagnosis has been frequently studied by Duplay, Sanger and Guinard. The only treatment is extirpation.

93. **Club-Foot in Children.**—In young children Shands holds that the cure of club-foot is comparatively easy, but after they have started to walk the difficulty is increased. The only requirement is a succession of plaster bandages properly placed, and this can be done with simply the assistance of the child's nurse. His method of applying the plaster and treatment is as follows:

> First apply a piece of cotton felt to both the outer and inner borders of the foot, extending it over the malleoli. This is done as an extra precaution for the protection of the bony prominences, being needed especially over the metacarpo-phalangeal joint of the great toe and over the cuboid bone—this being usually very prominent. Then apply at least two thicknesses of a canton flannel

bandage to the foot and leg, extending it to the tuberosity of the tibia. Now, having the foot and leg well protected, the plaster is applied also up to the tuberosity of the tibia. This will prevent the leg from moving in the plaster cast and giving a better leverage when the twisting process is begun. Care should be had to have the toes held in their natural relation to each other; otherwise you will have an uneven pressure, and, as a result, swelling and pain. The plaster should extend well over the toes, but their ends should be exposed. While waiting for the plaster to set, grasp the leg with one hand, holding it firmly on the table, and with the other press on the plantar surface with a piece of board; this serves the purpose of overcoming some of the deformity and gives a flat surface on which the child can walk better. When ready to begin the redressement cut out a wedge-shaped piece of plaster on the outer border of the foot over the most prominent part of the deformity, for here the greatest pressure is needed, then connect the upper and lower angles of this cut by cutting a line through the plaster entirely around the foot. Of course, it is intended that these cuts should extend only through the plaster. Care should be taken not to allow this cut around the foot to be near enough to the heel to allow the front part of the foot to move in the dressing when the foot is twisted, for then you would defeat the object in view. The plaster cast is now in two pieces, each firmly fixed to the foot. By grasping the leg with one hand and the end of the foot with the other, it takes but little force with this leverage to bring the opposite sides of the wedge-shaped incision into apposition, which corrects a certain amount of the deformity. While an assistant holds the parts in their new relation one to the other, they are fixed there by a wet plaster bandage applied around the foot and ankle in a figure-of-eight, care being taken to fill in well the gap made by the linear incision on the inner side of the foot. This third bandage being applied over a dry plaster cast, can be easily peeled off at the next sitting; then make the wedge-shaped incision larger, and repeat the redressement as before. This can be repeated three or four times, when it will become necessary to apply an entirely new dressing. Great care should be taken lest you get compressed between the edges of the plaster, when forced together, a fold of loose skin, which would likely cause a bad ulcer. This was learned by experience, for in one of my cases I had a bad ulcer that necessitated suspending the treatment until it was cured.

The number of sittings will have to be in accordance with the circumstances. Dressing should be done about three times a week until the foot is in a normal position and then once a week until the desired amount of over-extension is obtained, when a permanent dressing is applied and kept on, as a rule, for six months after the child begins to walk. When it is left off the closest watch should be kept, and as soon as there is any tendency to a return to the old conditions the foot should be put up again in a plaster cast. The treatment requires a great deal of patience and persistence and the cooperation of all parties. The surgeon must watch all details. He must make the parents divide the responsibility by impressing on them that they have a very important part to perform.

94. **The Action of the Uterus During Labor.**—Sothoron's theory of the action of the uterus during labor appears to be practically the same as one that has been suggested before, namely, that the circular fibers lose their power and become practically obliterated at the close of gestation, and the less-interfered-with action of the longitudinal fibers produces the delivery. It is not the action of the sphincter portion of the uterus that causes the labor.

95. **The Kidney in Pregnancy.**—This paper is based on urinary examinations in eighty-five women at various periods of pregnancy. Stewart claims from his findings that pregnancy does not cause so much disturbance as most authorities would have us believe; that is, that it is not a process that tends toward a destructive action of the kidneys. There must be the coexistence of secondary causes, if we choose to so call them, which tend to increased activity on the part of the kidney to a possible exhaustion of kidney tissue. In nearly all the cases where albumin was present, the unloading of the intestinal tract and incidentally of the kidneys, restored the patients to practically normal conditions. Pregnancy is a physiologic process in physiologically normal women. It is abnormal in many cases under our systems of education and training. To these we must look for the causes of albuminuria and nephritis.

97. **Dysentery Bacillus in Infantile Diarrhea.**—Wollstein finds that cases of infection by dysentery bacilli in infants tend to a clinical picture of dysentery with frequent mucous and bloody stools. In some cases of hospital infection following other diseases, especially pneumonia, and in other mild cases, the stools may not contain blood, but mucus is always present and in large amounts. The serum reaction is uncertain for one week, frequently positive after the sixth day, but may be absent for two weeks. It can not be relied on for early diagnosis in infants and young children. The only positive evidence during life is the isolation of the *Bacillus dysenteriæ* which is present in the stools for two or three weeks, but may remain longer. The type of organism almost invariably found in New York City is that of the Manila or Flexner bacillus.

100. **Proteolytic Enzymes.**—The deductions drawn from their study by Abbott and Gildersleeve are:

1. That the destiny of non-toxic, though otherwise physiologically characteristic products of bacterial life in the body, is determined by the presence of specific neutralizing substances that can be demonstrated in the circulating blood. 2. That, by the customary methods of artificial immunization, the amount of such antidotal substances in the blood may be increased, but only to a slight degree. 3. That, through the use of sera from animals, immunized from the non-toxic bacterial products, poor though such sera are in specific immune-body, it is possible to distinguish the proteolytic enzymes resulting from the growth of different bacterial species from one another, as well as from certain physiologically analogous enzymes of animal origin. 4. That the proteolytic enzymes elaborated by certain bacteria in the course of their growth are much more resistant to high temperatures than is generally supposed; some being capable of exhibiting their characteristic function after exposure in the moist state to a temperature of 100 C. for fifteen to thirty minutes. 5. That the so-called hemolysins of bacterial origin are, at least in some cases, probably proteolytic enzymes. 6. That it is possible by experimental means to contribute material support to the doctrine of Welch concerning the origin of "bacteriogenic cytotoxins."

108. **Mercurial Diuresis.**—From experiments on rabbits Tyrode and Nelson find they can not agree with Cohnstein's conclusion in regard to excessive diuresis from mercury. They find no difference in their results, whether the animal was anesthetized with chloral or urethan. The results were decidedly irregular on the animals. This explains to a great extent the discrepancies between the opinion of different clinicians as to the value of mercury as a diuretic. Without doubt, the individual difference in susceptibility to mercury is very great. The diuretic action is explained by two factors: The local irritation of the kidney and possibly an action on serous membranes influencing the absorption of fluids from them.

110. **Lead Poisoning.**—From the study of a case reported and of the literature, Spiller concludes that lead affects the brain and its pia, the nerve cells of the anterior spinal horns, the ganglia on the posterior roots, the peripheral nerve fibers and the muscles. It seems to be impossible to tell whether its effects are first manifested in the alteration of the peripheral motor fibers or of the motor cell bodies of the spinal cord, but since both peripheral motor fibers and motor cell bodies are sooner or later affected, the question is not important. The significance of the proliferation of endothelial cells of the capsules in the spinal ganglia and on the cerebral pia is difficult to determine.

1. Chorea.—Lees points out that there is much more of the brain affected than the Rolandic area in chorea. It is probably a disorder of the whole cerebral cortex, probably of the whole brain and possibly of the nervous system in general; not, however, a destructive one, but one usually ending in complete recovery. The morbid blood condition with which he thinks this is associated is rheumatism and both the disorders are probably due to the same infection. In support of this view he suggests that while the evidence is scanty, it is extremely suggestive; for example, a rabbit injected with a culture of the diplococcus to which rheumatism has been attributed develops something very closely resembling chorea in a child. Poynton has found the diplococcus in the cortex in cases of chorea though the cultural test was not effected, owing to the age of the specimen. Dana, Apert, Wassermann and others have isolated the diplococcus from the brain in fatal cases of chorea, though its identification with the rheumatic diplococcus has not been thoroughly made. He thinks, therefore, we can say that chorea is cerebral rheumatism in the great majority of cases, though the statement can not be made absolute for other toxins and microbes may possibly affect the cortex cells in the same way. It is even possible that sudden emotional disturbance may produce a toxin acting similarly. The difficulty in these cases, however, is to prove the absence of rheumatism. The deduction made from these facts is that the treatment for chorea and that of rheumatism should be similar. He therefore advocates the use of sodium salicylate with the addition of alkali, something like twice the amount of sodium bicarbonate as of salicylate of sodium to the dose. He thinks this combination is of considerable importance and in a great number of cases it has produced rapid improvement. The success seems to depend on the amount given daily. The dose of sodium salicylate for a child of 6 to 10 years should

be at first 10 gr. to 20 of sodium bicarbonate; after two or three days the quantity may be increased to 15 and 30 grains respectively; after two or three more days to 20 and 40 grains every two hours during the day and every three hours during the night; 10 doses in the twenty-four hours; thus increasing the daily dose from 100 gr. daily to 150 and finally to 200 gr. A careful watch should be kept for any symptoms of salicylate poisoning, especially for the peculiar deep inspiration. If this occurs medicines must be immediately given up, as it is a sign of danger. This air hunger symptom, however, is of rare occurrence. He believes this, with rest, is the most successful treatment for acute chorea. For chronic cases it may be less successful and time may be an essential factor. Arsenic in large doses sometimes produces distinct improvement, but he thinks there is the danger of arsenical neuritis. In the discussion Fisher noted some complications of chorea, especially the occurrence of cardiac lesions. Osler's experience is very similar. He shows that some facts seem to point to the probability that if the heart escapes during the first attack of chorea it is not likely to suffer in subsequent attacks, but some reserve should be held on this point.

Poynton pointed out the bacterial facts in regard to chorea, tabulating them briefly as follows:

1. Micro-organisms of the streptococcal group have been isolated from rheumatic fever. 2. They have been isolated from the cerebrospinal fluid and brain itself in chorea. 3. They have been demonstrated in the pia mater and brain. 4. Involuntary movements of a peculiar type have been recorded by Paine and myself and F. Meyer as resulting from intravenous inoculation of rabbits with such micro-organisms. 5. Identical bacteria are found in other rheumatic lesions in man, and are capable of producing the lesions of rheumatism in animals. 6. Chronic leptomeningitis has been noted in chorea by Dana. 7. The lesions found after death in acute chorea are such as one could explain on the view of an infection. I mean the minute thromboses and hemorrhages, occasional embolism, degenerative changes in nerve cells, and perivascular exudation commented on by Dr. Lees. These are, I admit, scanty and imperfect facts, but very suggestive ones. It would be a valuable contribution to our knowledge to have a detailed examination of the brain, in a series of cases of chronic rheumatic chorea. This is a difficult matter, but the finding of multiple focal lesions, such as have been discovered in Huntingdon's chorea, would add further evidence. How much of chorea is due to the focal lesions, and how much to the poisons of rheumatism, is at present a matter of speculation. I hold, however, to the view of chorea being an infection of the nervous system comparable to the infection of the nervous system in tuberculous meningitis rather than that of the nervous system in diphtheria paralysis. Though in entire agreement with Dr. Lees as to the association of rheumatism and chorea, I would not go so far as some and say it is always rheumatic. Remarkable cases of chorea after erysipelas, during tuberculous meningitis, and after measles, which I have met, make me very cautious on this point. As regards rheumatic fever and chorea I hold the view that one micro-organism is the cause.

2. **The Thyroid Gland and Marasmus.**—Ruhrah reports the results of studies of eighteen cases of marasmus. Excepting the terminal infection, atrophy of the thymus was the only lesion found in any of the necropsies. The changes consisted in marked atrophy with thickening of the capsule and trabeculæ. He reaches the following conclusions:

1. Atrophy of the thymus gland is always found in cases of infantile atrophy. 2. The condition of the thymus is an index of the general nutrition of the infant. 3. The state of the nutrition in infants may be estimated by a microscopic examination of the thymus at necropsy.

3. **Cleft Palate.**—Murray advocates early operation in cleft palate. Where there is a complete cleft both of the lip and palate he usually operates on the lip when the child is three or four weeks old, and delays operating on the hard and soft palate until the end of the second year. It is remarkable, he says, how closure of the lip influences the cleft of the hard palate. In a number of cases he has seen the alveolar gap practically disappear. This he thinks a good argument for delaying the operation on the palate; the narrower the cleft the easier the operation and the greater the probability of success.

4. **Congenital Dislocation of the Hip.**—The various methods of operation for congenital hip dislocation are noticed by Burghard, whose conclusions are given as follows:

1. All cases should be checked by radiography, and no "cure" should be spoken of that is not a true anatomical cure.
2. All cases of congenital dislocation under 14 years of age should be submitted to treatment. In the great majority improvement will result, while in some a true anatomical cure is brought about.
3. In all these cases Lorenz's manipulations should be tried in the first instance. Even should they fail to effect reduction, they facilitate any subsequent procedures.
4. The prospect of a cure by Lorenz's "bloodless method" is in direct proportion to the youth of the child, and after the age of 4 years there is little hope of a true cure by its means.
5. In any case, the chances of a true cure by the "bloodless method" are not very great.
6. An open operation should be done whenever a radiograph shows that the bloodless method has failed to reduce the dislocation, except, perhaps, in the case of a very young child—under 3 years—in whom the manipulations may be repeated.
7. With the open operation no fear need be entertained of shock, bleeding or sepsis.
8. Under no circumstances should the joint surfaces be remodeled.
9. An open operation is more calculated to result in a cure as it enables the surgeon to ascertain beyond a doubt when the head of the bone is really in the acetabulum.
10. The open operation is especially suited for cases over 4 years of age and for those of bilateral dislocation.
11. After the operation the limb should be put up in the position of maximum stability; in the majority of cases this will be similar to Lorenz's position. The limb should be put up in plaster of paris immediately, and the casing should take in the flexed knee; this is essential in order to ensure stability of the head of the bone.
12. All tense structures should be stretched or tenotomized as a preliminary measure a week or so previous to the open operation. The after-treatment is practically identical with that of the Lorenz method.

5. **Splenomegaly in Infants.**—It is pointed out by Carpenter that in very early life splenomegaly is frequent and occurs in about 40 per cent. of clearly syphilitic infants. He is inclined to think that Parrot's nodes are associated with splenic enlargement in about one-half of his cases of syphilitic manifestations. There are two important constitutional conditions usually associated with syphilis in infants and young children: 1. Syphilis; 2, rickets. There is also an undetermined cause or causes. There are difficulties, however, of excluding syphilis in some cases where the history is lacking. Syphilitic children are often not obviously anemic. Their color ranges from a doubtful pallor to a milk-and-water hue, with a bluish tinge about the lips, or to a lemon-yellow appearance. Petechiæ and bruises are not uncommon in the very severe cases, and lichen urticarius is not infrequent. Edema of the extremities and an occasional albuminuria were noted in some of the fatal cases. The relation of anemia to the spleen is not always perfectly clear. The liver is usually enlarged, sometimes trifling and sometimes markedly so. Some of the lymph glands may be slightly larger than normal. The prognosis depends on the blood condition. A great reduction in hemoglobin and in the number of the red cells, especially with alteration in size and form is not hopeful, and leucocytosis, apart from its being associated with a mild form of anemia, especially if marked, is not a good sign. Such children are liable to succumb to bronchopneumonia. In pernicious anemia the preponderance of megaloblasts over normoblasts is of bad omen. The characteristic of leukemia appears almost invariably to point to a fatal termination. The treatment should be preventive: proper food and hygienic environment. The anemia should be treated by fresh air, good food and the correction of bowel complaints. The rickets and syphilis require appropriate treatment. Of the drugs iron and arsenic are used as well as oxygen inhalations and seem to do good in some cases. A number of cases are reported.

7. **Tuberculosis in Children.**—Raw holds that man is attacked by two distinct varieties of tuberculosis: one by the infection of one person to another and the other by bovine bacilli in the milk or meat. He says primary intestinal tuberculosis, tabes mesenterica and other tuberculous affections of the serous membranes in children are probably bovine tuberculosis conveyed by milk and not related to the human tuberculosis. Tuberculous peritonitis cured by laparotomy is accounted for by him as localized bovine tuberculosis which has died out and the relief of fluid is sufficient to cure the patient. Bovine tuberculosis he believes is more virulent for children than the human tuberculosis. Scrofulous glands in the neck are also accounted for by him by the absorption of tubercle bacilli in milk through the tonsils or pharynx, and he thinks there is much evidence to suggest that acute miliary tuberculosis is also bovine in origin.

In the discussion, the rarity of tuberculous disease of certain types in India was mentioned by Reid, the medical officer of health of Tenby, taking his facts from the report of Dr. Crombie in 1899. The native habit of boiling all milk before using it, and the exclusion of beef from the food of a large

proportion of the native population would largely account for the infrequency of bovine tuberculosis in India, where tabes mesenterica is rare and tuberculous hip joint almost unknown.

12. **Yellow Fever.**—Tombleson gives the results of his experience in Mexico, where he has found a bacillus in the urine and blood serum of yellow fever patients, which closely resembles the Sanarelli form, though he says there is considerable difference in the descriptions of that type. As he has seen it, it is from one-half to two microns in length, the shorter form being found more particularly in the blood and cultures and the longer forms in the tissues and very old cultures. It is actively motile in its middle-sized forms, though hardly so in the longer forms. It stains well with all the ordinary stains, also with Gram's method. For demonstration in the tissues the best results are obtained by staining for one hour in toluidin blue, decolorizing with very faintly acid alcohol and counter-staining with eosin. It grows well on all the ordinary artificial media and in broth. It is very resistant to heat, which makes him think that it forms spores. Why it has not been oftener seen he thinks is possibly due to the fact that it is usually missed unless it occurs in very large numbers. He thinks there are times when it is more frequent in the blood than others. He has found it pathogenic in lower animals and to produce a very similar condition to yellow fever in a monkey. He thinks that it may be transmitted not only by *Stegomyia*, but also by the *Culex fatigans* or other foul feeding mosquitoes, taking up its spores. He believes that it is really the cause of yellow fever, and insists on its value as a method of early and certain diagnosis in doubtful cases, as well as on account of the evidence which it produces as to the means of spread of the disease. It is a proven fact, he says, of course, that certain mosquitoes carry the germ, but he thinks that beside this means of transmission, we must consider the possibility of the disease being spread by the inhalation of spores produced in the open air by the growth of the bacillus in urine, which is thrown on the ground in 99 cases out of 100. This explains how drainage has practically cleared Havana of yellow fever, while he does not think the number of mosquitoes is materially lessened there.

42 (No. 30.) *La phlegmatia alba dolens des typhiques et le régime hypochlorurique. A. Chantemesse.
43 *Recherches expérimentales sur les singes anthropoïdes. Roux and Metchnikoff.
44 Thoracèntèse, sans aspiration, au moyen d'un drain à valves formant soupape. Boinet.

42. **Cure of Phlegmasia Alba Dolens by Deprivation of Salt.**—Chantemesse found rapid improvement follow the systematic withholding of salt in cases of white swelling complicating typhoid fever. The results confirmed his theoretic assumption that the phlegmasia alba dolens in typhoid fever is the result of the intoxication of the limb by the salt retained in the organism during the course of the disease. His research verifies that of others in regard to the defective elimination of sodium chlorid in typhoid fever, and that the salt does not remain in the blood, but passes rapidly into the tissues. The connective tissue takes it up the more readily, as its vitality has been impaired by the infection. In 2 of his 6 typhoid patients treated by feeding them on unsalted meat bouillon, lactosed water and unsalted bread, the phlegmasia alba dolens had persisted for six and ten weeks and showed no tendency to improve under rest and the usual measures. Two other cases were recent and extremely painful. The swelling had followed thrombosis of the saphena. In the other cases there was thrombosis, but the swelling had not developed. All the patients showed marked improvement, and no swelling developed in the last 2 cases. The swelling subsided visibly from day to day, more rapidly in the recent cases. Return to salted food was invariably followed by a slight increase in the swelling. The coagulation in the veins seemed to soften and be absorbed more promptly than is customary in such cases. He believes that the thrombosis is merely the predisposing cause for the phlegmasia, which is essentially due to the local retention of sodium chlorid. He derived similar benefit in the case of an elderly woman who suffered from thrombosis in inflamed varices. There was retention of chlorids and slight albuminuria. The pain and tumefaction of the limb subsided completely after two days of unsalted food.

43. **Transmission of Syphilis to a Chimpanzee.**—Roux and Metchnikoff exhibited a young female chimpanzee which had been inoculated on the genitals with syphilitic virus from two syphilitic patients, from a chancre on one and from an ulcerated patch near a healed hard chancre on the other. Five days later she was inoculated with virus from a hard chancre only three days old. The points of inoculation soon healed and for three weeks there were no symptoms, but on the twenty-sixth day one of the points near the clitoris developed a chancre, and in the course of time the inguinal ganglia became enlarged, so that when the chimpanzee was exhibited, the forty-

sixth day, she presented a typical syphilitic chancre, acknowledged to be such by Fournier. He remarked that he was almost ready to burn his ships behind him and proclaim that the transmission of syphilis to an animal had been accomplished, but that he believed after all he would wait to see whether secondary symptoms develop before final judgment, although he granted that the lesion resembled in every respect a typical chancre and the duration of the incubation also coincided with that of syphilis in man, as also the pleiad of enlarged glands, four on one side and three on the other. The glands have also the characteristic dry hardness and are absolutely indolent. Roux and Metchnikoff expressed their gratitude for the large sums of money recently awarded to them in the Osiris and the International Medical Congress prizes, which enabled them to conduct this research. They think the positive result is due to the choice of an animal so closely resembling man as the anthropoid chimpanzee. Fournier mentioned the model monkey house installed at one time in Dr. Krishaber's residence where he had inoculated large numbers of ordinary small monkeys with simple chancre, with success in 62 per cent. of 142 inoculations. He then proceeded to inoculate the monkeys with syphilitic chancre, but not one of the 20 animals responded positively to the inoculations.

50 Sur une forme de ptosis non-congénital et héréditaire. Delord.

47. Tuberculous Rheumatism in Children.—Bentz describes and illustrates cases of what he decided by exclusion to be tuberculous rheumatism. The affection took the arthralgic form in 2 cases of Pott's disease, and after the rheumatism had subsided, the latter continued its course apparently unmodified by the former. Beside these cases he observed one of rheumatism in the foot and knee on the side opposite a tuberculous hip affection, and a fourth case of rheumatic arthralgia in the shoulder, elbow, knee and foot, accompanying a tuberculous knee lesion. Not the slightest benefit was derived from sodium salicylate in any of these cases, although the pains and symptoms simulated those of acute rheumatism in the joints involved. He also observed a case of a chronic arthritis in both knees co-existing with a suppurative osteitis of the left tibia and progressing to recovery without presenting any of the characteristics of a white swelling.

48. Operative Treatment of Elephantiasis of Scrotum.—Marques shows in 5 cuts the various steps of Saboia's method of removing the excess of tissue in this condition. He has performed the operation himself thirty times and seen it performed a hundred more. The results have always been highly satisfactory in every respect. When the operation is completed the scrotum is of the normal size and shape with merely a Y-shaped sutured incision as traces of the intervention. The arms of the Y embrace the root of the penis. There is seldom much hemorrhage, and it is readily controlled. The co-existence of a hernia renders the outlook less favorable, otherwise it is a simple, easy operation.

52 French and German National Statistics of Mortality and Morbidity.—Etablissement de tables nationales de mortalité et de morbidité en France et en Allemagne.

51. Are Contagious Disease Hospitals Centers of Infection for Their Neighborhood?—Farnarier publishes a number of diagrams showing the mortality from infectious diseases in the various wards in Paris. It is evident at a glance that certain wards suffer much more than others from diphtheria and, to a lesser extent, from scarlet fever. It is also shown that these wards are the ones that contain the hospitals for diphtheria and scarlet fever cases. The fact is thus established that diphtheria certainly, and scarlet fever probably, do radiate from hospitals where cases of these diseases are admitted. He discusses whether such institutions should be removed to the outlying parts of the city, and concludes that there is no occasion for the inconveniences of such an extreme measure. It would be sufficient to prevent contagion, he thinks, to have such hospitals built in the form of small, isolated pavilions, surrounded with trees, and fenced in to allow a wide "dead space" around them.

60 Der Berliner Pest-Fall in seiner epidemiologischer Beziehung. F. Plehn.

53. Fall Catarrh.—Dunbar is convinced that he has fully established not only the etiology of hay fever, as previously announced, but also that of fall catarrh. He remarks that this affection does not occur elsewhere than in the United States, and is due to the pollen of the golden rod, rag-weed, hog-weed, etc. The toxin of these pollen grains differs from that of the pollen of the graminaces to which he attributes hay fever. At the same time, the symptoms of irritation induced by the pollen of the golden rod were rapidly cured by the grass pollen antitoxin which he is producing. (See THE JOURNAL, p. 139.) He has found that hay fever asthma was promptly relieved in many cases by external application of the pollen antitoxin to the nose. He prepares the antitoxin now in the form of a powder and reports good results from it. The patients do not become accustomed to its use, and it has never induced any injurious by-effects in his experience, not even on the kidneys.

54. The Berlin Plague Serum.—Martini reviews the literature on bacteriologic diagnosis of the plague and reports the technic and tests of antiplague serum. The serum made at Berlin is bactericidal.

55. Bactericidal Properties of Radium Rays.—The tests described were made with only 15 mg. of radium bromid, but they established that the rays possess a positive inhibiting action on cultures of typhoid and cholera germs under certain conditions.

56 and 57. Report of Tuberculosis Tests by Special Committee.—Bovine bacilli induced first a local, then a general infection, but bacilli from human tuberculosis never caused more than the local lesion in 19 tests with pure bouillon cultures from sputa or tissue from severe cases of tuberculosis, as also from 7 cases of bone, neck and urogenital tuberculosis which Koch has suggested may be similar to the *Perlsucht* in cattle. The results of the tests were different in 2 out of 6 cases of miliary tuberculosis. Four calves inoculated with a pure culture of tubercle bacilli from a miliary tuberculosis of the mesenteric glands of the same child, all exhibited dissemination of the lesions over the body, as in *Perlsucht*, although not quite so violent. The same result followed inoculation of a second culture derived from a caseous gland in the neck. General infection resulted. The results of the inoculation were negative in tests with pure cultures from 7 cases of intestinal tuberculosis, with the exception of 2 cases in which the cultures seemed to be very pathogenic for calves. They were derived in one case from a caseous abdominal gland in a child who had succumbed to scarlet fever, and in the other from a child who had died with peritonitis. These cases displayed such pathogenic power for calves that Kossel accepts that they must have been cases of infection of the children with bovine tuberculosis, that is,

Perlsucht. In all, tubercle bacilli from 39 different sources were examined, including 16 children. With 19 there was not the slightest evidence of pathogenicity; with 9 a local focus was induced, with no tendency to dissemination. With 4, all derived from children, a general infection resulted which ran a course similar to mild bovine tuberculosis infection. In only 2 of the 4 had the death of the child been due to the tuberculous process. Orth refers to his similar experiments, which resulted in general infection of 2 calves out of 5 inoculated with human tubercle bacilli. He remarks that it is for Koch now to explain why his experiments all resulted negatively when others always obtain a certain proportion of positive results.

58. **Bacteria of Whooping Cough.**—Arnheim reiterates his claims made three years ago in regard to the specificity of the bacteria isolated by him from the throat of children with pertussis. In 8 cadavers he found the laryngeal and pharyngeal mucosa inflamed with hemorrhagic points and foci of these bacteria. He did not find any specific substance toxic for the nerves.

59. **Gall-Bladder Colic Without Gallstones.**—In Krukenberg's 2 cases no stones were found, but the gall bladder seemed to be abnormally movable.

64. **Bactericidal Properties of Bone Marrow.**—Hencke proclaims that the bone marrow has very pronounced bactericidal power and frees itself of bacteria more rapidly and more effectually than the internal organs. He also states that he found a bacillus in 5 cases of spontaneous osteomyelitis, which invariably reproduced the typical affection in rabbits after intravenous injection without trauma.

65. **Vaccination of Guinea-Pigs Against Tuberculosis.**—Levy found that virulent bacilli of human tuberculosis became avirulent when kept for forty-eight hours in an 80 per cent. sterilized solution of glycerin, at a temperature of 37 C. Injected into guinea-pigs, these bacilli caused the formation of an abscess, but this soon healed. A series of five intraperitoneal injections of these glycerinated bacilli practically vaccinates them against tuberculosis infection. Injection afterward into the axilla of an otherwise fatal dose of virulent human tubercle bacilli, fails to induce more than a mild, rapidly-healing lesion. Not a trace of general tuberculosis could be discovered in the animals when dissected later. He made these injections into the axilla under conditions approximating as closely as possible those that prevail in human tuberculous infection.

75. **Suture of Heart.**—Wolff states that 39 cases have now been recorded of suture of the heart and the results indicate that suspicion of a stab wound of the organ imposes operative intervention, even in the absence of vital indications, as a prophylactic measure. On the other hand, wounds from firearms may be treated expectantly. In the former case the pleura has almost invariably been opened, and, therefore, it is not necessary to operate extrapleurally. The pericardium should be sutured, the tampon used only when the wound is infected. The button suture has proved most effective; the threads tied during the diastole. The left ventricle is most favorable for an operation of this kind as the patients are not so liable to bleed to death on the spot. The case reported by Pagenstecher confirms Bode's experimental research, demonstrating that the nourishment of the heart does not suffer materially after ligature of a coronary artery. Wolff reports 3 cases of suture of the heart, with 2 recoveries, and states that this brings the total on record to 42, with 17, that is, 40.4 per cent. recoveries. Only 1 was a firearm wound. Fischer's statistics showed that only 10 per cent. recovered in the unoperated cases. Wolff adds that intervention may be necessary and successful even in the absence of an external wound as witness a case described in the *Lancet* in 1897. A young man was kicked in the breast at football. Unconsciousness persisted and the heart dulness kept on increasing. The pericardium was incised and found filled with blood, but bleeding from the heart had ceased. After the blood had been drained away the young man was fully restored and was able to join in the game again.

77. **Drainage of Pelvic Abscesses Through Sciatic Foramen.**—Schmidt found that the foramen is easily and conveniently reached through an incision as for a Kocher resection. The results of draining by this route in the 3 cases described showed the feasibility and advantages of the procedure.

83 Traumatic Rupture of Heart. Revenstorff.—Ueber traum. Rupturen des Herzens mit bes. Berücksichtigung des Mechanismus ihrer Entstehung.

78. **Spleen Tumor and Hyperglobulia.**—Rosengart describes the case of a man of 41 who had suffered for a long time from oppression in the heart region, dyspnea and vomiting. The blood was thick and dark red, specific gravity 1,072, hemoglobin 190 to 200. There were 10 million reds and 12,000 whites, all apparently of normal composition. The spleen was very much enlarged, and there was a peculiar purplish coloring of the face, hands and visible mucosæ. Venesection relieved the symptoms temporarily, but was abandoned after a few trials for fear it might incite to renewed regeneration of the blood, as it is known sometimes to do in chlorosis and anemia. Treatment with iodin to relieve the circulatory disturbances was supplemented by dieting to "un-iron" the patient, restricting him to sugar, rice, cereals, peas, dates, figs, plums and nuts. After eight months the reds had diminished by 1 million, the hemoglobin had fallen from 200 to 150 and the whites from 12,000 to 10,000. The outline of the spleen was still 30 by 15 cm. Rosengart believes that the syndrome was due to a primary tuberculosis of the spleen, and suggests the possibility that splenectomy might prove as effectual in such cases as in splenic anemia. The hyperglobulia he regards as a secondary reaction on the part of the bone marrow. He has found 6 cases on record of primary tuberculosis of the spleen.

In one it was a pure, primary tuberculosis of the organ; in 3 there was primary tuberculosis of the spleen and secondarily of the liver. In another the diagnosis was not certain, and in the other the details are too meager. Türk has reported a case of ten years' duration in which the hemoglobin when examined was 180 per cent. and the specific gravity 1,070.

79. **Appendicitis Obliterans.**—Faber states that the microscopic findings in appendices removed on account of chronic inflammation are identical with those discovered casually at autopsies which some regard as the results of senile involution.

80. **Respiratory Disturbances in Exophthalmic Goiter.**—Hofbauer distinguishes between the primary disturbances and those induced secondarily by mechanical compression of the trachea by the struma—cardial and bronchial asthma or hysteria. The primary are characterized by the shallowness of the respiratory curve, protracted inspiration and expiration, irregularity in the shape and size of the curves, with intervals of pauses in the respiration, more or less complete. There is another form of the primary disturbances characterized by paroxysmal, rapid, deep breathing, likewise with pauses. He attributes both to the functional disturbance of the thyroid gland, which is responsible for the disease, and is inclined to endorse the possibility of combating this morbid secretion of the thyroid with the milk or serum of thyroidectomized animals.

104 Toxin and Antitoxin. P. Ehrlich. (Concluded.)

84. **Importance of Catatonic Symptoms for Prognosis.**—Meyer believes that catatonic phenomena render the prognosis of a psychosis grave, but not necessarily absolutely bad. In his experience with 46 cases in which they were included in the clinical picture one-fifth to one-fourth of the number recovered their health—by the layman's standard of health—for a number of years. There were hereditary influences at work in about 54 per cent., and most pronounced in the cases with the least favorable outcome.

85. **Diagnosis of Liver Abscess After Dysentery.**—Schlayer was frequently able to affirm with almost certainty by the hyperleucocytosis the presence of an abscess in the liver. He says that in 11 cases of acute or subacute abscess the leucocytes ranged from 18,000 to 62,000 the days before the operation, averaging 25,000, with a single exception. The lack of hyperleucocytosis was frequently a valuable sign for exclusion of liver abscess in puzzling cases of typhoid or malaria.

86. **Banti's Disease.**—Fichtner analyzes a case which he had opportunity to observe through several years. A previously healthy young man received a blow in the left stomach region. The pains persisted for weeks, and the spleen became much enlarged. During the following seven years he was debilitated and presented a hypertrophied spleen, severe, rebellious otitis, varying anemia and ascites, with occasional gallstone colic. Both the anemia and ascites retrogressed so much that operative intervention was not advised. The last examination, however, showed 92 per cent. hemoglobin, 4,060,000 reds and 3,458 whites. The spleen had slightly increased in size, but there was no ascites. The case shows that the connection between the spleen tumor and the changes in the blood is not so close as Banti assumes, otherwise the anemia would have been much more intense in comparison with the size of the spleen. The fluctuations in the intensity of the anemia, considered with reference to the constantly progressive increase in the size of the spleen, indicate that the blood changes are not secondary to the spleen affection but must have some other special cause.

87. **Widal's Reaction in Case of Icterus.**—Köhler's researches detract from the reliability of the Widal test as the reaction was obtained in 12 out of 100 non-typhoid cases. It was particularly marked in liver affections with icterus. Bile gives the reaction, also, but comes more under the head of chemical reactions. Catarrhal icterus may modify the blood serum and induce a positive response to the test, especially when the infection is due to the colon bacillus. Puerperal fever, sepsis, coli abscesses, intestinal catarrh and coli metastases are all liable to lead to errors in diagnosis from this cause. Agglutination may occur, therefore, not only with typhoid, but also with liver affections, accompanied by stagnation of bile and the passage of bile into the blood, and also when the organism is under the action of certain chemicals, or of the colon bacillus, and, possibly, of other bacteria.

88. **Operative Treatment of Uterine Cancer.**—Sippel thinks that the development of operative technic has reduced the dangers from abdominal section to such a low point that it now ranks with vaginal intervention. He restricts vaginal hysterectomy to cases in which the cancer is in the corpus, if not too far advanced, and also cases of incipient carcinoma of the portio.

90. **Medical Oversight of Orphan Asylums, Etc.**—Siegert refers to the fact that Strasburg stands at the head of German cities in respect to its care of the children with its numerous vacation colonies, children's hospitals, etc. He describes the workings of the official medical inspection of all children in any way the wards of the community. All orphans and other dependents under 2 years of age must be brought to the dispensary appointed for inspection at intervals of one to eight weeks as directed. The child is examined, weighed and the details recorded in regard to its food, growth, frequency of meals, the influence of the maternal constitution on the child, the prodrome and symptoms of disease, its development, the particulars of teething and the disturbances connected therewith, the development of the static functions and other particulars. These examinations of such large numbers of children, both the sick and the well, at stated periods, and the careful records kept of each case can not fail to throw light on some still disputed questions.

91. **Subcutaneous Injuries of Kidney.**—Bechtold reports a favorable termination in each of the three cases he describes. Hematuria was the prominent symptom. In 2 the traumatism affected both the front and back, and the injury was probably due to hydraulic pressure. One of the patients was 85. The complete transient retention of urine was probably the result of reflex action from the injured kidney on the other one.

92. **Improved Technic of Radioscopy.**—Among the points mentioned are the use of a "giant tube" and of a stand like an ordinary screen, only more solid. A sheet of lead slides vertically up and down in the frame of this screen, with an adjustable diaphragm in the center. A sheet of ground glass

is fitted over the fluorescent screen, and after the former is wet, the outlines of objects seen through the fluorescent screen can be marked on it with pencil. The advantages of the technic described are that all the side radiating rays are eliminated, and only those used that fall directly on the part to be examined. Also that the subject can move to bring the various aspects of the part before the screen, as he is not fastened to it in any way.

93. **Hypnosis and the Medical Profession.**—Forel pleads for instruction in psychology in the medical curriculum, with special reference to the value of a knowledge of hypnosis to the general practitioner. He concludes with the statement that hypnotism and waking suggestion are one and the same thing, and that it is the duty of the medical profession, of science and of the colleges, to study them and enlighten the public in regard to them. How can physicians learn to know the functions of the brain, which has such a preponderant influence on all the functions of the body, when psychology, psycho-physiology and hypnotism are so systematically ignored in general medical instruction. In consequence of the ignorance in this domain, many morbid phenomena in stomach, intestines, uterus and elsewhere are erroneously diagnosed and locally treated when the actual auto-suggested cause lies in the brain mechanism, and can be removed only by acting on this mechanism.

94. **Prophylaxis and Treatment of Puerperal Fever.**—Fehling found that the difference in morbidity was only slightly in favor of the use of gloves, 7.1 per cent. of 197 cases with, and 9.8 per cent. of 224 women examined without gloves. His assistant, Schuhmacher, has published statistics of 500 examinations of hands which showed that streptococci were never present on the nails after the disinfection in the clinic. Palmer has recently reported that an interval of eight days is not enough to destroy streptococci on the hands of obstetric nurses. For these and other reasons, including the absence of injury of the parts from the nails, Fehling advocates and uses rubber gloves in making examinations, and requires all his aids to use them. He always carries a couple of pairs of rubber gloves around with him and uses them where there is the least suspicion of infecting his hands. This keeps them comparatively clean, and the Fürbringer method of disinfecting will complete the sterilization. Since following and enforcing this plan he had only 1 case of severe infection and 8.47 per cent. morbidity in 802 cases of childbirth in 1902, while in 1901, before the glove régime was adopted, there were 5 severe cases and morbidity of 11 per cent. in 802. He thinks that operative procedures offer little prospect in puerperal sepsis, and his experience was negative with inunctions of colloid silver salt, but intravenous injections of the colloid silver were certainly effective to a certain extent. Not all the patients thus treated recovered, but the temperature and pulse were favorably influenced and likewise the general condition, and he thinks this treatment deserves serious consideration. He injected 10 to 20 c.c. of a 2 per cent. solution into a vein in the elbow. All were subjectively benefited. If the severe symptoms recurred he repeated the injection every day, sometimes for eight or ten days. But the main reliance will always be on prophylaxis, he adds, rubber gloves for every kind of vaginal or rectal examination and clean hands for operative interventions.

97. **Resuscitation of Suspended Heart Action.**—Velich describes a method suggested by Professor A. Spina of Prague which offers a prospect of resuscitating persons after sudden death from some temporary cause. He reviews the history of attempts to revive the suspended heart action in animals and man, and notes many interesting points published in the results of the researches of various investigators. Kuliabko's resuscitation of animal hearts and of the isolated heart of a three-months' infant, twenty hours after death, has already been mentioned in these columns, March 21, 1903, page 813. Velich has repeated these experiments on the hearts of animals, and his experience confirms that published by others. He found that the heart taken from a young dog and buried in snow on the outer window sill for eighteen hours could be made to resume its contractions by forcing Locke's solution at 95 F. through it. Another heart was placed in physiologic salt solution, and the fluid allowed to freeze over. The next morning the dish was brought into a warm room, and after the ice had melted, twenty-four hours after the heart had been removed from the living animal, it began to pulsate in a few minutes after the warm Locke solution had been flowing through it. The auricular appendages first gave signs of pulsation, then both auricles and then the ventricles showed feeble vibrations. These experiments show that there is little difference between the heart of cold-blooded and of warm-blooded animals in respect to the resistance to cold. They also indicate that the main factor in restoring heart action is the filling of the vessels with fluid. Massage of the exposed heart is only liable to prove successful if the heart can be filled with blood, by compression of the abdominal vessels or by injection into an artery of physiologic salt solution at 95 to 104 F. Professor Spina has accomplished this in dogs, injecting 200 c.c., directing the stream toward the heart. It forces the blood along before it, and when the semilunar valves are reached, the stream closes them. This closes the entrance into the left ventricle and drives the blood into the coronary arteries, through which it circulates exactly as in the experiments with resuscitation of the isolated heart by Langendorff's method. In this manner he was able to restore the heart action in a large number of animals, even in those whose cerebrospinal system had been destroyed and those that had succumbed to the action of alcohol or other poisons. In one experiment a curarized dog was injected with nicotin, and after the subsidence of the phenomena induced by this poison, the artificial respiration was suspended. The heart ceased to beat in a few minutes. The thorax was opened and the heart seen to be absolutely still. Ten minutes later artificial respiration was resumed, and 200 c.c. of physiologic salt solution containing 1 per cent. grape sugar was injected into the external iliac artery, directed toward the heart. Even while the injection was being made, the heart began to pulsate, and soon the blood was circulating as in a normal dog. The results of these experiments indicate that Spina's method is applicable to man in case of sudden death from any cause in which it is possible that the spark of life can be fanned into a blaze again by injecting the blood vessels of the heart in this manner, and thus tiding it over the critical moment of some temporary injurious influence.

99. **Treatment of Hematocele.**—Zweifel has found that the women who had been treated expectantly recovered after absorption of the blood with restoration of almost complete integrity of the parts, most surprising when the pathologic conditions at the time are considered as noted in other women during operations. He operated on 46.5 per cent. of his 211 cases observed between 1890 and 1899. There was no mortality. The unexpectedly favorable ultimate results found in the unoperated cases, he remarks, will render him more conservative in regard to operating in the future. Each patient is now informed that she will recover eventually without an operation, but that the latter will relieve her of pain and much shorten the convalescence. It is left for her to decide in most cases. He adds that if some means could be found which would hasten absorption, then there would no longer be any question of operating. Hydrotherapy and repose are about our only reliance, although he always uses iodin.

100. **Adrenalin as a Preliminary to Spinal Cocainization.**—Bier, the originator, or rather the rediscoverer, of spinal anesthesia, has always been most earnest in protesting against the assumption that the technic had been perfected past the danger point. He used to remark that the sanguine French and the daring Americans maintain that this has been realized, but he did not agree with them. He has been constantly studying the subject since his first communication, and the announcement is now made from his clinic that an important step toward this ideal has been made in recent tests of adrenalin injected previous to the cocain. He found that the toxicity of cocain could be reduced by one-third by the addition of three drops of adrenalin to the fatal dose of cocain for

cats (.018 gm.), while injection of the adrenalin six minutes before the cocain was injected, reduced the toxicity of the latter to one-fifth. Dönitz states that he injected three times this quantity of adrenalin subcutaneously into his own arm to find if it could be tolerated. He presented symptoms of a slight general intoxication for a few minutes but all had vanished in thirty to forty-five minutes, except that the acceleration of the pulse persisted a little longer. Braun has already announced that adrenalin enhances the anesthetic action of cocain. By combining them it is possible to complete the anesthesia with much smaller quantities of the cocain. Spinal cocainization of a number of patients, after previous injection of .5 c.c. of the 1 to 1000 solution of adrenalin, induced complete anesthesia with only .0075 to .015 gm. of the cocain. The anesthesia was fine in all, allowing major operations, and there were no by-effects in the majority, and when they occurred they were insignificant.

105. **Flexible Intestinal Sound.**—Experience is confirming the great value of Kuhn's flexible spiral sounds. He here expatiates on the advantages and proper method of using his intestinal sound. It is a stiff or a soft sound at will, and it is impossible to kink it. A thin-walled rubber tube of Nélaton rubber is the outer envelope of the tube proper, which consists of a metal ribbon of copper bronze wound in a spiral, with a steel guide inside.

108. **Peptic Ulcer in Esophagus.**—Hödlmoser analyzes the various theories that have been advanced for the etiology of peptic ulcer of the esophagus, and describes a case personally observed in which a simultaneous peptic ulcer in the duodenum confirmed the diagnosis. The patient was a day laborer, 35 years old, who had suffered for several years from gastric disturbances, accompanied latterly by pain in the lower sternal region and difficulty in swallowing. The pains in the stomach continued with varying intensity and there was occasional vomiting of "coffee grounds." Lavage of the stomach showed extreme stagnation and dilatation of the organ. Blood finally began to appear in the vomit and death followed in progressive anemia. Kraus has collected 20 similar cases, and notes that in the majority there were no symptoms to suggest the presence of an ulcer in the esophagus, the symptoms being referred to the stomach. Fränkel has reported 2 cases of stenosis of the esophagus consecutive to a peptic ulcer, and calls attention to the length of time that elapses after the first symptoms of disturbance before there is any indication of stenosis. The triad, vomiting of blood, pains in the lower sternal region and difficulty in swallowing, should certainly suggest this affection, especially when associated with indications of stenosis.

109. **Paroxysmal Tachycardia.**—Frick presents arguments to establish the central origin of paroxysmal tachycardia, and mentions among them that pressure on the vagus, either by deep breathing, by Valsalva's test or otherwise, will arrest the attack. He explains this phenomenon by assuming that the tachycardia is the result of some paralyzing influence on the extra-cardiac heart center of the heart-retarding fibers in the medulla oblongata, while, at the same time, the heart-accelerating fibers are stimulated to extra exertion. Pressure on the right vagus sends a stimulus through its centripetal fibers to the center and this proves sufficient to arouse it from its lethargy and enable it to send through the left vagus its heart-retarding impulse. This impulse continues after the pressure on the vagus is removed, as the center once aroused does not relapse into its lethargy. Deep breathing or the Valsalva test has the same effect as pressure on the vagus. It is not to be wondered at that these heart centers in the brain become functionally deranged in case of morbid irritation from a diseased heart, and that this functional derangement gradually becomes rectified as the condition of the heart improves. In 2 cases of paroxysmal tachycardia under the writer's observation he found it possible to abort or arrest the attacks by compression of the right vagus, which the subject can learn to apply himself. One patient was a consumptive, and compression of the vagus promptly arrested the attack after it had lasted an hour. The pulse dropped from 198 to 72 at once, and then rose to 110, the subject's normal rate.

113. **Prophylaxis of Syphilis.**—Weitlaner describes two instances in his experience in which entire families were infected with extragenital syphilis by a child taken in to board. In a third case the manager of a "baby farm" was infected by one of the infants in her charge, and is liable in turn to infect all the other inmates of her establishment. This extragenital infection usually manifests itself first in the mouth or throat, as it occurs by way of spoons or dishes used in common. The habit of tasting the food to test the temperature before giving it to the infant is undoubtedly responsible in many cases. In conclusion he suggests the necessity for continued oversight over illegitimate children born in maternities.

116. **The Placenta in Syphilis.**—All the articles in this number of the *Wochenschrift* are dedicated to Rudolf Chrobak on the occasion of his sixtieth birthday. Hitschmann and Volk have carefully examined 22 placentæ from women known to be syphilitic. They also review the literature on the subject. They were unable to discover any alterations in the placenta specifically characteristic of syphilis.

117. **Rapid Bossi Dilatation of Cervix.**—Experiences with 5 patients at Schauta's clinic failed to show any advantage from the use of the Bossi dilatator. On the contrary, the time required for the necessary anesthesia is a great drawback. The dilatation does not resemble the physiologic process and lacerations are liable to occur.

118. **Hot-Air Treatment of Gynecologic Affections.**—The efficacy of dry heat in reducing pain and promoting absorption has been established to Burger's satisfaction from his experience with a number of cases treated by electric baths or application of superheated air. In 8 out of 12 cases of chronic perimetritis of six months' to nine years' standing the patients were soon relieved of the pains in the sacral and lumbar region and felt better generally. In 5 of these improved cases the palpation findings were altered by the treatment. The improvement was rapid and pronounced in 13 out of 14 cases of parametritis. The patients were all remarkably relieved and in most cases the objective improvement was also evident. An important point in this class of cases is that the hot-air treatment causes the retrogression of the parametritic tumors and thus allows discovery of lesions higher up, in case they exist. The subsidence of pain is probably the result of the active hyperemia. In several cases of inflammatory processes in the adnexa the inflammatory edema retrogressed, and a case of actinomycosis was favorably influenced, as also 3 cases of abdominal fistula persisting after a laparotomy. Under the influence of the hot air applied to the fistula, which was first dried and dusted with iodoform to prevent scalding from steam, the wound began to granulate normally and rapidly healed. The menses were hastened by the action of the hot air in some cases, suggesting its application in amenorrhea.

119. **Leucocyte Count in Gynecologic Affections.**—Waldstein and Fellner tabulate the findings and blood count in 29 cases of various gynecologic affections. Comparison of the details shows that pus-containing tumors of the adnexa in the acute stage are accompanied by leucocytosis. It persists longer than the fever, but subsides in time, notwithstanding the continuance of the pus pocket. Tumors in the adnexa not containing pus are not accompanied by leucocytosis. Thirty-five cases of other gynecologic affections were examined from this point of view and a number with internal hemorrhage, etc. The results showed that much loss of blood from myoma or extrauterine pregnancy may induce a hyperleucocytosis, the more pronounced the greater the hemorrhage. If the organism has time to produce more blood to take the place of what is lost, as in case of small, repeated hemorrhages from a myoma, the leucocytosis may be moderate or imperceptible. On the other hand, in case of much loss of blood, as from rupture of an extrauterine pregnancy, the leucocytosis may be as intense as in case of pus formation. In one case it reached 24,000, a few hours after the operation it was 23,000, and as the patient regained strength it fell to 16,000. In 2 cases of a four weeks' hematocele, the leucocytes numbered 12,000. In 2 other cases examined four to six weeks after tubal abortion the blood count was normal.

120. **Extramedian Symphysiotomy.**—Van de Velde has coined the term "hebotomy" for this operation, which he remarks was first suggested by Champion eighty years ago, but has only become practicable since Gigli invented the wire saw. It has been performed 12 times to April, 1903. All the mothers recovered with no disturbances and their gait is as perfect as before. All the children were delivered alive. The great advantages of this intervention are that the wound can be protected from contact with the urine and vaginal secretions, and that the sawing of the healthy pubis is followed by a healthy callus formation, which holds the sawed edges apart and thus permanently enlarges the deformed pelvis. In one of his cases he purposely left a gap between the sawn edges the width of a finger. The woman was up in three weeks, had no pain and resumed her life as a working woman in six weeks. A radiogram four months later showed that the pelvis was permanently enlarged, the urethra, clitoris and symphysis permanently asymmetrically displaced to one side, with a difference of 2 cm. from the spin. ant. sup. to the symphysis on the two sides. The pelvis is as solid as ever, and in this case, as with his previously operated patients, the excess of callus is gradually absorbed so that in time there is no trace of the intervention. In case a second hebotomy is required it might be made on the other side, and thus the pelvis be permanently enlarged by 3 to 4 cm., which is the maximum that should be striven for.

121. **Influence of Castration on Blood of Female Animals.**—For three years Breuer has been studying on dogs the effect of removal of the ovaries on the composition of the blood. He found that castration has an unmistakable effect on regeneration of the blood in younger animals, from seven to ten months old. Older ones were not affected. The ovaries have, therefore, an undoubted influence on the composition of the blood. The disturbances produced by their extirpation bore no resemblance to human chlorosis. He believes that this research is an important support of the genital origin of chlorosis.

124. **Epidural Injections in Treatment of Enuresis.**—Kapsammer reports the details of 37 cases of enuresis treated by epidural injections according to Cathelin's method, recently described in THE JOURNAL, page 527. He has made 300 epidural injections, and has never seen a reaction except twice; once the patient vomited once afterward, probably because the injection had been made too rapidly and was somewhat larger than usual. In the other case the patient vomited twice the day after the injection and the point of the injection was slightly painful. He disapproves of Cathelin's advocacy of epidural injections as a "universal remedy," but thinks that for enuresis the results far surpass all others. He recommends two or three injections at brief intervals, even when the cure seemed to be complete after the first. He proclaims, however, that a saline solution has exactly the same effect as the cocain and may be used in its place. A remarkable feature of this treatment, already noted by others, is that an excessive desire to urinate is reduced and deficient desire stimulated. His experiences have confirmed those of all the others who have tested the method as to its complete harmlessness. The 25 cases completely cured which he describes in detail include 19 with enuresis nocturna and 6 with both nocturna and diurna. The cure dates from fourteen months in 1, ten months in 1, more than six months in 2 and five months in 6; 8 patients were cured by a single injection. Six had been treated by a number of other methods without result. Some of the cases required several injections, one as many as 13 and one 12. He thinks that these latter cases could have been cured quicker if he had injected larger amounts at shorter intervals. Fourteen of the 25 were treated with cocain solution and the others with saline. One was an infant less than 2 years old, consequently the effect can not be ascribed to suggestion; another was a man of 25 with pollakiuria diurna and enuresis nocturna, both cured by 2 cocain injections. Another was a lad of 16 cured by 4 cocain injections of enuresis, both night and day, since early childhood. In a second series of 6 cases the patients left before the final result could be ascertained, and although cured when last seen, are not included in the statistics, as also 6 others still under treatment.

134. **Technic of Laparotomy.**—Gruzdeff has long advocated copious flushing of the abdominal cavity with saline solution before closing it after a laparotomy. In 28 cases in which the abdomen was treated by the dry method there were 3 deaths, while only one patient died in the 72 cases in which he followed his method of irrigation, and this fatality was due to other causes. He prefers Locke's solution for the purpose as more nearly approximating the composition of the blood plasm, and pours it into the abdomen three or four times, swabbing out the cavity each time with gauze sponges, and finally leaving a large amount in the abdomen after it is sutured. He thinks that by this means the abdominal cavity is not only cleaned, but the germs that may have found their way in during the operation are washed out and the phagocytes are stimulated to more energetic action. A still further advantage is that the pressure in the abdomen is maintained by the fluid left behind, and it does not tend to collapse after the removal of large tumors. His series includes a variety of indications, as he relates in detail. The pregnancy was not interfered with in one patient on whom a laparotomy was performed on account of peritonitis.

135. **Stomach Digestion in Icterus.**—Simnitzky found that retention of bile from any cause had a marked influence on the digestive processes in the stomach, always inducing hypersecretion until the stomach became exhausted by the chronic course of the affection, after which hyposecretion was the rule. His clinical experience was confirmed by experiments on animals.

137. **Ligation of Carotid for Traumatic Hemorrhage.**—A bullet wound in the neck suppurated and recurring hemorrhages compelled Miklashevsky to ligate the left common carotid artery. This seemed to be well tolerated at first, but after a month hemiplegia developed on the right side, evidently from some focus of softening in the region whose nutrition had been disturbed by the ligature, after anastomosis had been established. The hemiplegia gradually subsided. He has found 914 cases on record in which the common carotid had been ligated, in 337 for the removal of a tumor, in 75 on account of aneurism, in 335 for hemorrhage, and in 54 for neuralgia. About 39.8 per cent. of the patients succumbed to the progress of their affection. The mortality of ligation *per se* has been computed by Hueter at 5 per cent.

138. **Seacoast and Sun Baths in Surgical Tuberculosis.**—Bobroff reports most gratifying results from the sanatorium for children which was established in the Crimea mainly through his efforts. The sea air in this balmy climate, sun and sea bathing are all important factors in the treatment of localized tuberculosis. He lays great stress on direct exposure of the site of the lesion to the sunshine, protected merely by a sheet.

139. **Outlining the Stomach by Inflation.**—Sievert examined 25 subjects, some healthy and others with gastric lesions, to determine the value of this method of diagnosis. He found that the stomach does not distend equally in all directions when gas is generated in it with soda and tartaric acid. The distension seems to be greatest towards the right side. When a moderate amount of gas is formed the findings coincide with those obtained by percussion, auscultation, etc., but if large amounts are generated then the organ is abnormally distended and the findings are not those of the actual condition. This procedure, however, has the advantage that it enables the outlines of the stomach to be determined by the eye.

141. **History of Atmocausis.**—Professor Sneguireff was the first to apply steam to the local treatment of gynecologic affections. During the fifteen years since a long array of communications on the subject have been published, which are reviewed in the present article. Atmocausis, or vaporization as it is called, has proved of signal value in arresting hemorrhage during operations on the liver, in climacteric uterine affections, for cauterizing the uterine mucosa, etc. Pincus and Dührssen have been particularly successful with it in various gynecologic affections; the former advocates it as an ideal means of obliterating the uterine cavity.

142. **Treatment of Fecal Fistula.**—Grekoff describes a case in which exclusion of a portion of the intestine with persisting fecal fistula into the sac was followed later by hernia of the excluded portion, requiring its resection. Two normal pregnancies had occurred in the interim. He recommends resection as an indispensable supplement to the primary intervention, praising the Maisonneuve method of enteroanastomosis as the simplest and least aggressive.

144. **Thermotaxis of the White Corpuscles.**—Mendelssohn proclaims that he has established that the white corpuscles are attracted by heat. This thermotaxis is most pronounced at a temperature of 36-39 C. (97 to 102 F.), but is still marked at 25 to 35 or even 20 to 25 C. In inflammations, therefore, the leucocytes are attracted by thermotaxis as well as by chemotaxis, he believes. Temperatures higher than 102 F. did not seem to attract them.

146. **Psychologic Conditions for Hypnosis.**—Rybakoff ascribes to emotion the chief rôle in the production of the hypnotic sleep. This assumption is sustained by the changes in the heart action and respiration, the subjective sensations during the hypnosis and the fatigue afterward. This condition of emotion enables the subject to respond to the will of the hypnotizer and is the most important requisite for a successful hypnosis. Other causes contribute only as they induce this emotion.

HIGH-FREQUENCY CURRENTS IN THE TREATMENT OF SOME DISEASES. By Chisholm Williams, F.R.C.S. Edin., M.R.C.S. Eng. Cloth. Pp. 222. Price, $2.75, net. London and New York: Rebman, Ltd. 1903.

FOOT AND MOUTH DISEASE. By D. E. Salmon, D.V.M., Chief of Bureau of Animal Industry. Paper. Reprint from Nineteenth Annual Report of the Bureau of Animal Industry. 1902.

REPORT OF THE TRUSTEES OF BELLEVUE AND ALLIED HOSPITALS for Quarter Ending March 31, 1903. Paper. Pp. 22. New York: Mail and Express Company. 1903.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., for the week ending Saturday, Sept. 5, 1903:

Birmingham, Henry P., major-surgeon, is detailed for duty as chief surgeon on the staff of Major-General J. C. Bates during the Army maneuvers to be held in the vicinity of West Point, Ky., and will report by letter to that officer for instructions. Major Birmingham will proceed at such time and to such place as may be designated by Major-General Bates.

Bising, A. G., is granted leave for one month.

Cable, G. L., contract surgeon, is relieved from further duty at Fort Clark, and will proceed to his home for annulment of contract.

Harmer, J. R., contract surgeon, is granted leave for two months.

Ireland, M. W., major-surgeon, will report to the commanding officer Third Battalion Engineers for duty with the headquarters, staff and Companies L and M of that battalion while en route to San Francisco, and, on the completion of this duty, will return to his station in Washington, D. C.

Sabin, W. E., contract surgeon, is assigned to temporary duty at Vancouver barracks.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending Sept. 5, 1903:

Asst.-Surgeon O. Kohlase, Sept. 10, 1903, detached from duty at the Naval Hospital, Mare Island, Cal., and ordered to duty at the Naval Museum of Hygiene and Medicine, Oct. 1, 1903.

Asst.-Surgeon R. K. McClanahan, en route home from Asiatic Station, via the *Solace*.

Asst.-Surgeon C. M. Oman, detached from the *Solace* and ordered to the *Monadnock*.

Asst.-Surgeon H. A. Dunn, detached from the Naval Station, Cavite, P. I., and ordered to the *Solace*.

Asst.-Surgeon R. A. Bachman, ordered to the Naval Station, Cavite, P. I.

Asst.-Surgeon F. M. Munson, ordered to the *Frolic*.

Asst.-Surgeon H. F. Strine, ordered to the *Isle de Cuba*.

Asst.-Surgeon J. L. Neilson, ordered to the *Iris*.

Marine-Hospital Changes.

Official list of the changes of stations and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the fourteen days ended Sept. 3, 1903:

Surgeon J. A. Gassaway, Department letter granting him leave of absence for two months from August 10, amended to read two months from August 13..

Surgeon G. W. Stoner, granted seven days' leave of absence from August 29, under paragraph 189 of the Regulations.

Surgeon H. R. Carter, Bureau letter granting him leave of absence for thirty days from August 4, amended so as to read twenty-four days from August 5.

Surgeon G. M. Magruder, granted leave of absence, on account of sickness, for thirty days from Sept. 7, 1903, or so much thereof as may be necessary.

Surgeon R. M. Woodward, granted two days' leave of absence from Aug. 20, 1903, under paragraph 189 of the Regulations.

P. A. Surgeon M. J. Rosenau, detailed as chairman of Working Party No. 2, Yellow Fever Institute, and directed to proceed to Vera Cruz, Mexico, for special temporary duty in connection therewith.

P. A. Surgeon M. J. White, relieved from duty at Portland, Ore., and directed to proceed to Honolulu, T. H., and report to medical officer in command for duty, relieving Asst.-Surgeon J. M. Holt. Granted leave of absence for three days from September 5.

P. A. Surgeon L. D. Fricks, to proceed to Baltimore and report to Surgeon H. R. Carter for temporary duty in connection with the inspection of immigrants at that port.

P. A. Surgeon H. B. Parker, relieved from temporary duty at Washington, D. C., and, as chairman of Working Party No. 2, Yellow Fever Institute, and directed to report to P. A. Surgeon M. J. Rosenau, and to proceed to Vera Cruz, Mexico, for duty under his direction.

Asst.-Surgeon H. A. Stansfield, on being relieved from duty at Mariveles, P. I., to proceed to San Francisco, and report arrival by telegraph.

Asst.-Surgeon J. M. Holt, on being relieved from duty at Honolulu, T. H., to proceed to Manila, P. I., and report to P. A. Surgeon V. G. Heiser for duty.

Asst.-Surgeon C. W. Vogel, relieved from duty at San Francisco, and directed to proceed to Manila, P. I., and report to P. A. Surgeon V. G. Heiser for duty.

Asst.-Surgeon C. W. Wille, on completion of duties at Baltimore, to proceed to Philadelphia and assume temporary command of service at that port during absence, on leave, of Surgeon F. Irwin.

Asst.-Surgeon J. W. Amesse, on being relieved from duty at Jolo, P. I., to proceed to San Francisco and report arrival by telegraph.

Asst.-Surgeon M. W. Glover, granted leave of absence for one month from September 8.

Asst.-Surgeon Edward Francis, relieved as temporary chairman of Working Party No. 2, Yellow Fever Institute, and directed to report to P. A. Surgeon M. J. Rosenau as member of Working Party No. 2 on his arrival at Vera Cruz, Mexico.

Asst.-Surgeon R. H. Creel, relieved from duty at Immigration Depot, New York, and directed to proceed to Manila, P. I., and report to P. A. Surgeon V. G. Heiser for duty.

A. A. Surgeon L. C. Bean, granted leave of absence for two days from September 4.

A. A. Surgeon D. M. Echemendia, granted leave of absence for seven days from Aug. 20, 1903, on account of sickness, under paragraph 210 of the Regulations.

A. A. Surgeon L. P. Gibson, granted leave of absence for six days.

A. A. Surgeon S. B. Hunter, granted leave of absence for six days.

A. A. Surgeon W. A. Kimmet, granted leave of absence for two weeks from August 25.

A. A. Surgeon W. J. O'Reilly, granted leave of absence for three days from September 8.

A. A. Surgeon R. H. Peters, granted leave of absence for twenty days from August 4.

Pharmacist W. F. Macdowell, granted leave of absence for thirty days from September 14.

Pharmacist W. L. Stearns, granted leave of absence for thirty days from September 8.

Pharmacist G. A. Morris, to report to chairman of board of examiners at Fort Stanton, N. M., Sept. 12, 1903, for examination to determine his fitness for promotion to the grade of pharmacist of the second class.

Pharmacist F. Siedenburg, granted leave of absence for thirty days from September 5.

BOARDS CONVENED.

Board convened at Fort Stanton, N. M., Sept. 12, 1903, for the examination of Pharmacist G. A. Morris, to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the board: Surgeon P. M. Carrington, chairman; Asst.-Surgeon J. W. Trask, recorder.

Board to meet at Washington, D. C., on call of the chairman, to consider certain matters relative to uniform regulations of the Service. Detail for the board: Assistant Surgeon-General A. H. Glennan, chairman; Assistant Surgeon-General G. T. Vaughan, Assistant Surgeon-General H. D. Geddings, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Sept. 5, 1903:

SMALLPOX—UNITED STATES.

California: Sacramento, Aug. 6-23, 2 cases; San Francisco, Aug. 16-23, 1 case.
Colorado: Denver, July 25-Aug. 15, 6 cases.
Illinois: Chicago, Aug. 22-29, 4 cases, 2 deaths.
Indiana: South Bend, Aug. 22-29, 1 case.
Massachusetts: Fall River, Aug. 22-29, 1 case.
Michigan: Marquette, Aug. 22-29, 1 case; Port Huron, Aug. 22-29, 1 case.
Mississippi: Natchez, Aug. 22-29, 1 case.
New Jersey: Camden, Aug. 22-29, 1 case.
Ohio: Dayton, Aug. 22-29, 3 cases.
Pennsylvania: Erie, Aug. 15-22, 1 case; Pittsburg, Aug. 23-30, 95 cases, 13 deaths, 1 case imported.
Texas: San Antonio, July 1-31, 14 cases.
Utah: Salt Lake City, Aug. 15-22, 1 case, imported from Idaho.
Virginia: Pocahontas, Aug. 22-29, 1 case.
Wisconsin: Milwaukee, Aug. 22-29, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, July 11-18, 1 case, 1 death.

SMALLPOX—FOREIGN.

Belgium: Brussels, Aug. 8-15, 3 deaths.
China: Shanghai, July 11-18, 1 death.
Colombia: Barranquilla, Aug. 8-16, 3 deaths.
France: Paris, Aug. 1-8, 1 death.
Great Britain: London, Aug. 8-15, 9 cases; Manchester, Aug. 8-15, 1 case; Newcastle-on-Tyne, Aug. 8-15, 10 cases, 1 death; South Shields, Aug. 8-15, 1 case; West Hartlepool, Aug. 8-15, 2 cases.
India: Bombay, July 28-Aug. 4, 5 deaths.
Mexico: City of Mexico, Aug. 16-23, 9 cases, 5 deaths.
Russia: Moscow, Aug. 1-8, 2 cases, 1 death; Odessa, Aug. 8-15, 1 case.

YELLOW FEVER—UNITED STATES.

Mississippi: Gulf Quarantine, Sept. 1, 1 death, from schooner Henrietta G. Powell from Vera Cruz.

YELLOW FEVER—FOREIGN.

Colombia: Panama, Aug. 17-24, 3 cases, 1 death.
Costa Rica: Limon, Aug. 13-30, 4 cases, 2 deaths; San Jose, Aug. 13-30, 2 cases; Zent, Aug. 13-30, 4 deaths.
Mexico: City of Mexico, Aug. 16-23, 1 death; Linares, Aug. 24, 14 deaths; Merida, Aug. 9-15, 10 cases, 5 deaths; Progreso, Aug. 15-22, 2 cases; Monterey, Aug. 26, 1 case; Tampico, Aug. 16-22, 19 deaths; Tehauntepec, Aug. 9-15, 4 cases, 3 deaths; Teran, Aug. 27, present; Salina Cruz, Aug. 9-15, 3 cases, 2 deaths; Valladolia, Aug. 9-15, 1 case; Vera Cruz, Aug. 8-22, 112 cases, 44 deaths.

CHOLERA—INSULAR.

Phillippine Islands: Manila, July 11-18, 7 cases, 7 deaths; Provinces, July 11-18, 1,369 cases, 825 deaths.

CHOLERA—FOREIGN.

China: Hongkong, July 15-22, 1 death.
India: Calcutta, July 25-Aug. 1, 12 deaths.
Turkey: Damascus, July 21-Aug. 18, 57 deaths; Damascus Province, July 21-Aug. 18, 312 deaths; Tripoli, July 25, present.

PLAGUE—INSULAR.

Hawaii: Honolulu, Aug. 18, 1 death.
Philippine Islands: Manila, July 11-18, 1 case.

PLAGUE—FOREIGN.

China: Hongkong, July 15-22, 18 cases, 9 deaths.
India: Bombay, July 28-Aug. 4, 100 deaths; Calcutta, July 25-Aug. 1, 12 cases; Karachi, July 26-Aug. 2, 2 cases, 2 deaths.

THE VARIOUS METHODS OF PRESERVING AND MOUNTING GROSS EYE PREPARATIONS.*

CASEY A. WOOD, M.D.

CHICAGO.

Early methods of preserving the enucleated eyeball and other ocular tissues were very crude. The specimen was generally placed in a bottle of ethylic or methyl alcohol of unknown strength, which not only bleached and hardened the tissues, but rendered them useless for future microscopic sections. Shrinking of the globar walls and intraocular structures proceeded until the parts became unfit for use, either as museum preparations or for other teaching purposes. Attempts were now and then made, by the addition of glycerin and other agents to the alcohol, to retard these changes, but with little permanent success. Bichlorid solutions, Müller's fluid and other chromate preparations were found to be improvements on the alcohol mixtures, but even these were not satisfactory, requiring constant care and frequent changing of the fluid, else the tissues were not affected by stains subsequently used for microscopic sections. In any case the cornea became opaque, the iris discolored, the other parts stained, and only the coarsest changes in the bisected globe, such as tumors, dislocated lenses, detached retinæ, etc., could be distinguished. Indeed, it was not until Priestley Smith devised his well-known plan of preparing and mounting the divided eyeball in a glass receptable containing gelatin that a decided advance was made in the preservation and exhibition of gross specimens.

Preparations of thick sections of the eyeball may be preserved, although not as effectively as in specimen jars, by placing them on discs of opal glass over which a little prepared and melted jelly has been poured. The specimen is now covered with more jelly, air bubbles are removed by pricking them, and when the mass is hard enough a plano-convex lens is attached to the surface of the specimen just as one would apply a cover glass.

DRY METHODS OF PREPARATION.

An ingenious plan was that of Hyrtl. He pierced the optic nerve of the enucleated eyeball and through the opening expressed the intraocular contents. The hollow globe was then inflated and dried. Beyond demonstrating the size and shape of the eye this method is useless, and has long been abandoned.

A more profitable proceeding is to harden the divided globe in alcohol, dehydrate by any suitable method and soak for ten days in turpentine. At the end of this time the tissues will be quite transparent. Now allow the turpentine to evaporate slowly. Such a specimen, if merely protected from dust, will keep indefinitely and will, especially when examined with a lens, show the tissues almost as well as in any of the preparations about to be described. However, these preparations degenerate in time, owing to injury from handling and from exposure to dust and smoke.

THE PRIESTLEY SMITH GELATIN METHOD.

The eyeball, generally preserved in Müller's fluid, is frozen,[1] divided by means of a sharp razor and, when required, immersed in a 2 per cent. chloral-hydrate solution to remove at least a part of Müller's stain. This procedure is repeated every day or two until no staining of the immersion fluid results. To prevent shrinkage of the half eye when it is placed in the jelly, it is next given, for 24 hours each, a bath of 10, 25 and 50 per cent. glycerin. It is now (concave surface up) transferred to the glass jar, which should be about half filled with the melted gelatin. When the fluid jelly has entirely filled the hemisphere it is turned over so that its plane surface is accurately applied to the bottom of the specimen jar. Great care must be observed to prevent the retention of air bubbles within the globe or in the gelatin surrounding it. When the jelly is hard the jar is carefully filled with more gelatin.

The jelly consists of Coignet et Cie's gelatin, 1 part, glycerin and water, of each, 8 parts by weight. Slowly dissolve the gelatin in the water by the aid of gentle heat; add the white of one egg; boil thoroughly and filter through flannel. Finally, stir in the glycerin, to which has been added 0.1 per cent. of carbolic acid. The jar covers may be of ordinary clear glass, or of the white opalescent variety, cemented by means of four parts of gutta percha and one part of pitch. The jars were originally made by and can be had of Messrs. Osler, Broad street, Birmingham, England. Treacher Collins suggested that a plano-convex lens be cemented on the upper surface of the jars by means of Canada balsam. This arrangement enlarges considerably the intraocular image and shows the minor details of the specimens. At the request of the committee several gentlemen (whose efforts contributed much to the success of the exhibit at New Orleans and whose practical experience permits them to speak with authority) have furnished a description of their favorite methods of mounting macroscopic eye preparations.

Dr. George Sloan Dixon[2] published an article on the "Preservation of Macroscopic Eye Specimens," most of

* Report of the Committee on Exhibit of Pathologic Preparations at the Section on Ophthalmology, American Medical Association, New Orleans, May 5-8, 1903. Casey A. Wood, Chairman; H. V. Würdemann and E. A. Shumway.

which is here reprinted with an addendum giving a few modifications made by him since its publication. This monograph furnishes a complete description of the formalin-jelly method of preparing the Priestley Smith mounts. It will also be seen that, in many respects, it is a decided improvement over the original mode of preparation.

The preparation of macroscopic eye specimens was very unsatisfactory until the advent of formalin as a hardening reagent. Time is also greatly economized by the use of formalin, as it requires but twenty-four hours to effect the preliminary hardening.

Formalin will not harden the vitreous, although it has the property of rendering this substance less viscid. For example, if an eye be removed from the formalin bath at the end of the first twenty-four hours and divided, the normal vitreous will be of a consistence similar to thin syrup, and is sure to be lost during subsequent manipulation.

In the majority of instances the loss of vitreous is of no great importance, but a more nearly normal macroscopic specimen will of course be obtained if it be preserved, and in some cases it is quite necessary. Therefore, in specimens where it is desirable to retain the vitreous, alcohol must be employed.

Another advantage obtained by the use of formalin, especially in intraocular tumor specimens, is that the

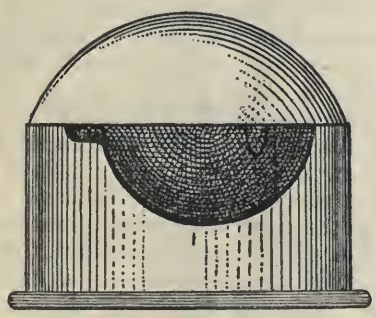

Fig. 1.—Treacher Collins' modification of the Priestley Smith jar.

finished mount shows the original colors to have been almost wholly retained, very little bleaching occurring.

As soon as possible after enucleation puncture the globe at or near the equator with a small knife, in order to admit the fluid, and place it in a wide-mouth bottle containing a little absorbent cotton, and enough of a 10 per cent. solution of formalin in distilled water to cover it. Allow the eye to remain in this solution for twenty-four hours, and then transfer it to weak alcohol, 25 per cent. to 50 per cent., depending on the density of the globe, and increase the strength of the alcohol by about 10 per cent. daily. An inclination to collapse is an indication that the alcohol is being increased too rapidly. When the strength of the alcohol has reached 80 per cent., allow the specimen to remain in it for four days, or indefinitely if intended for future use. At the end of this time the vitreous will have become sufficiently dense to permit division of the globe without loss.

The next step in the progress is to remove the alcohol in order to permit the globe to be frozen. This is done by placing it in from ten to twenty times its volume of water for twenty-four hours. It is well to change the water at least once, though this is seldom necessary. When the globe has settled to the bottom of the vessel, sufficient alcohol will usually have been removed to allow freezing.

The freezing box should not be less than seven inches square—nine inches is a very good size. It should have a few holes in the bottom for the purpose of drainage.

Remove the globe from the water, dry it carefully with a soft towel or piece of gauze, cut off the nerve close to the sclerotic and draw an ink line from cornea to nerve on both sides to indicate the direction desired to cut. In the majority of instances the horizontal plane is selected. Wrap the globe in oiled silk, without pressure on the globe. Fill the box with mixed pounded ice and salt, deposit the globe in the middle, cover and allow it to remain in a cool place for one hour. Remove the globe, rest it on a piece of cork and divide it quickly with a thin sharp knife in the line previously drawn, being careful not to employ more sawing motion than is absolutely necessary, and further, do not rest the cornea on the cork.

Having divided the globe, place the hemispheres in distilled water to thaw. After ten or fifteen minutes remove the half selected for microscopic examination to 25 or 50 per cent. alcohol, and gradually increase the strength from day to day until 80 per cent. has been reached, where it may remain awaiting the further treatment required for imbedding. At the same time transfer the half selected for the macroscopic specimen to a 5 per cent. aqueous solution of chloral hydrate for twenty-four hours; glycerin and one-third water twenty-four hours; finally, equal parts of glycerin and water for twenty-four hours, when it will be ready to mount in glycerin jelly.

The formula for glycerin jelly has been repeatedly published, but as ordinarily made it almost invariably has a marked amber tinge. This may be due to the quality of the gelatin used, but we think this is frequently caused by the material through which it is filtered, flannel usually being recommended. The best quality of (so-called "French Gold Label") gelatin should be used, and nothing containing color should come in contact with the jelly during its preparation—even the shells of the eggs employed should be rejected if not pure white.

The following method of preparing the jelly has been uniformly successful in our hands, and we, therefore, give it in detail: Take gelatin, 1 part; water, 8 parts, and glycerin, 8 parts.

We generally add a trifle more gelatin, say 0.5 per cent. Cut the gelatin into small pieces, place in a glass vessel with a very wide mouth (fruit-jars are unreliable—agateware works well), add the water, cover and let it stand for an hour, then place the whole in an Arnold sterilizer, or in a water bath, and apply only sufficient heat to dissolve the gelatin. When dissolved stir in the albumin of one fresh egg (with its shell if white) for each ℥viii. Replace in the sterilizer and boil until complete separation has occurred. Filter hot through absorbent cotton. A hot-water funnel is useful for this purpose. If the filtrate is not absolutely clear repeat the operation. The glycerin is then added, and also enough carbolic acid to preserve it—not more than 3i of a 10 per cent. aqueous solution for each ℥vi of jelly.

If carefully made in this manner the jelly will be almost free from color, and of about the same index of refraction as the glass of which the macroscopic cups are made.

The jelly should be kept in two flasks, a large one for stock and a small one for use from day to day; both should be closed with cotton-wool plugs. The larger (or stock) flask should be heated only when necessary to fill

the smaller one. Exclude light as much as possible. If evaporation occurs to any considerable extent before the jelly has been used, a little sterilized distilled water can be added.
